### Background

Workers' Compensation Medical Protocols first became effective on January 1, 1996 as a result of legislative changes to Section 31-280 of the Workers' Compensation Act. The Workers’ Compensation Commission (WCC) uses these Medical Protocols to evaluate whether a particular treatment is reasonable and appropriate based on the diagnosis of a worker’s injury or illness.

Revisions to various Medical Protocols reflect the latest changes in the medical field regarding new procedures, treatments, and diagnostic tests:

- Protocols for treatment of injuries to the cervical spine and lumbar spine were revised in 2012 and updated in 2013 and in 2015.
- Protocols for treatment of injuries to the knee were revised in 2015.
- Protocols for treatment of injuries to the hand, wrist, and elbow were revised in 2015.
- Protocols for treatment of injuries to the shoulder were revised in 2014.

Additionally, Opioid Management Protocols were created in 2012, because the WCC recognizes that some injured workers may require opioids to manage their acute and chronic pain. Proper opioid management is essential for the safe and efficient care of injured workers. The Opioid Management Protocols were revised in 2017.

### New

In consultation with practitioners, insurers, and the Medical Advisory Panel, new Medical Protocols for Psychological Pain Assessment and Treatment became effective in 2016 to assist practitioners in effective pain management for injuries occurring within the workers’ compensation arena.

Revisions to various Medical Protocols reflect the latest changes in the medical field regarding new procedures, treatments, and diagnostic tests:

- Protocols for treatment of injuries to the cervical spine and lumbar spine were revised in 2012 and updated in 2013 and in 2015.
- Protocols for treatment of injuries to the knee were revised in 2015.
- Protocols for treatment of injuries to the hand, wrist, and elbow were revised in 2015.
- Protocols for treatment of injuries to the shoulder were revised in 2014.

### Effective Dates

- March 27, 2017: Opioid Management – revised
- February 15, 2016: Psychological Pain Assessment and Treatment – created
- November 1, 2015: Cervical Spine Lumbar Spine – update
- August 15, 2015: Knee – revision
- April 1, 2015: Hand, Wrist, and Elbow – revision
- April 1, 2014: Shoulder – revision
- July 1, 2013: Cervical Spine Lumbar Spine – update
- July 1, 2012: Cervical Spine Lumbar Spine – revision
- July 1, 2012: Opioid Management – created

### Future Updates

The WCC advises practitioners, insurers, and other concerned parties to periodically check for announcements of revisions and updates on the WCC website: [wcc.state.ct.us](http://wcc.state.ct.us)

The WCC – with practitioners, insurers, and the Medical Advisory Panel – is currently revising the Workers’ Compensation Medical Protocols for the treatment of injuries to the foot and ankle, and these will be published upon completion.

### Acknowledgments

The WCC thanks the medical professionals who have spent – and continue to spend – many hours working with us to bring the most appropriate treatment, and the highest standard of care, to injured workers in Connecticut.
# INTRODUCTION

Pain is a complex phenomenon. Many factors contribute to and modify pain.

It is generally accepted that pain generators include both somatic and psychic elements. These factors are further modified by complex social variables.

What is generally referred to as "pain" by most laypersons is a subjective experience. As such, "pain" is a psychological experience and product of complex biopsychosocial phenomena.

Consequently, the diagnosis of the causes of "pain" and associated treatment of "pain" is an enormously challenging endeavor often complicated by insistent demand for relief. Neither biological / medical, psychological, nor environmental / social strategies may suffice.

It is clear from the literature that the highest rates of diagnostic and treatment efficacy are represented by integrated biopsychosocial and interdisciplinary models and delivery systems.

Psychological approaches to diagnosis and treatment appear to many to be a "black box." However, even casual scrutiny reveals similar uncertainties, ambiguities, and knowledge limitations in biological / medical methods.

Psychological / neuropsychological procedures for assessment and treatment of emotional, behavioral, and motivational aspects of pain continue to evolve in accuracy and efficacy.

Inclusion of these methods in an integrated approach to pain management is increasingly and widely recognized as essential.

---

## PROTECTED HEALTH INFORMATION

Protected Health Information in the psychological domain enjoys a higher level of HIPAA protection than general medical information.

All health care providers responsible for collection, storage and dissemination of Psychological Protected Health Information have a legitimate and formal obligation to support these standards.

Providers must familiarize themselves with the operational details of these obligations and implement them rigorously in their clinical settings.

Generally, this is accomplished by the identification and segregation of Psychological Protected Health Information with distinct procedures and documents for authorization of information release.

---

## RECOMMENDED TIMELINES

As with all the recommendations the timelines are to be taken as guidelines and not mandates.

It is recommended that the greatest flexibility and discretion be given to providers’ application of the diagnostic criteria in the earliest care time frame of INTAKE TO 4 WEEKS.

The vast majority of patients in the workers’ compensation system flow through the system of care without complication.

The recommended baseline demographic data is meant to be collected as early as possible to enhance focus on those patients for whom any complication, or question of potential complication, may arise.

The timing of initial collection and documentation of these demographics will vary according to the type of treatment venue and the associated baseline population characteristics.

Optimal timing in any given clinical setting will be responsive to the earliest possible thresholds for potential treatment complications.

---

## FORENSIC CAVEATS

Advanced diagnostic procedures and technologies allow for objective measurement and documentation of symptom over- and under-reporting, dissimulation of psychopathology, and malingered neurocognitive impairment.

It is neither cost-effective nor conducive to clinical care to prematurely implement forensic assessment.

It is similarly ineffective to delay forensic assessment despite repeated and ongoing indications of diagnostic / claim invalidity.

When properly designed and implemented the entire continuum of psychodiagnostic data collection contributes to a stepwise incremental evaluation of symptom validity.

The formal administration of a detailed and objective forensic assessment simply represents the final phase of this systematic analysis and, as such, is integrated into the entire continuum of care.
### INTAKE TO 4 WEEKS (with consideration of date of injury)

#### DIAGNOSTIC CRITERIA

Demographic screening to identify:
- any previous psychological diagnosis / treatment, including:
  - psychiatric hospitalization
  - outpatient psychotherapy / counseling
  - psychopharmacological treatment (e.g., antidepressants, anxiolytics, etc.)
- diagnosis and / or treatment of any drug or alcohol abuse or dependence – e.g., life interference such as:
  - relationships
  - work
  - DWI
  - detoxification
  - inpatient / outpatient rehabilitation
  - 12-step participation
- prior treatment for work-related pain
- prior workers' compensation claim with pain-related lost time

Physician discretion based on anomalies of case presentation or course . . .

AND / OR

. . . positive response to any one of 4 questions obtained by any provider (above)

#### DIAGNOSTIC STUDIES

Recommended:
- monitor medical progress
- refer for psychodiagnostic interview:
  - positive responders on demographic screen
  - individuals based on physician discretion

#### TREATMENT

Recommended:
- medical monitoring
- implementation of psychodiagnostic interview-generated recommendations

#### GOALS OF TREATMENT

Medical regimen compliance with:
- expected decreased VAS ratings
- functional improvement
<table>

**Diagnostic Studies**

Psychodiagnostic interview:
- by qualified psychological / psychiatric provider
- with administration of standardized screening tools, such as:
  - ODI
  - BDI

**Treatment**

Recommended, per examination results:
- continued medical management
- enhanced monitoring
- rehabilitative psychotherapy
- compliance contingency management regimens
- emotional-behavioral contraindications to medical management – e.g.:
  - primary / secondary gain
  - polypharmacy
  - interventional procedures including:
    - injections
    - blocks
    - surgery

**Goals of Treatment**

Support medical treatment goals with:
- enhanced medical regimen compliance
- pain reduction
- functional improvement

<td><strong>Recommended, per examination results:</strong>&lt;br&gt;• continued medical management&lt;br&gt;• enhanced monitoring&lt;br&gt;• rehabilitative psychotherapy&lt;br&gt;• compliance contingency management regimens&lt;br&gt;• emotional-behavioral contraindications to medical management – e.g.:&lt;br&gt;  – primary / secondary gain&lt;br&gt;  – polypharmacy&lt;br&gt;  – interventional procedures including:&lt;br&gt;  o injections&lt;br&gt;  o blocks&lt;br&gt;  o surgery</td>
<td><strong>Support medical treatment goals with:</strong>&lt;br&gt;• enhanced medical regimen compliance&lt;br&gt;• pain reduction&lt;br&gt;• functional improvement</td>
</tr>
</tbody>
</table>
# Greater Than 6 Months

## Diagnostic Criteria
- continued failure to demonstrate functional improvement
- lack of response to pharmacological strategies
- lack of response to interventional strategies
- marked noncompliance
- marked litigiousness
- failed drug screen
- repeated loss of medications
- other compromises of medication contracting
- positive findings on PMP

## Diagnostic Studies
Recommended:
- forensic examination:
  - by qualified psychological / neuropsychological provider
  - include:
    - systematic analysis of ability suppression
    - systematic analysis of response bias
    - formalized battery of screening measures
    - forced choice measures
    - self-report inventories with validity scales (IME?)

## Treatment
Recommended, per examination results:
- continued medical management
- enhanced monitoring
- rehabilitative psychotherapy
- compliance contingency management regimens
- emotional-behavioral contraindications to medical management – e.g.:
  - primary / secondary gain
  - polypharmacy
  - interventional procedures including:
    - injections
    - blocks
    - surgery

## Goals of Treatment
Support medical treatment goals with:
- enhanced medical regimen compliance
- functional improvement

Cessation of care, on the basis of:
- documented unreasonableness
- unnecessary evaluation
- unnecessary treatment
## Procedure Base Criteria

MEDICAL PROTOCOLS: OPIOIDS – PAGE 1 of 5

OPIOID MANAGEMENT OF THE INJURED PATIENT

OVERVIEW

Proper opioid management is essential for the safe and efficient care of injured patients. The WCC recognizes that some injured patients may require opioids for the management of their acute and chronic pain. It is not the intention of the WCC to restrict the proper medical use of this class of medications, however responsible prescribing is mandatory. Additionally, studies have shown that injured workers placed on high dose opioids early in the post-injury period may experience a slower recovery, more difficulty with returning to work, more difficulty with weaning, and more frequently end up on long term opioids.

During the first two weeks post injury, low dose, short acting opioids may be appropriate for those with more severe injuries. Even during the acute phase it is preferred that the injured worker avoid opioid medications when possible. During the remaining portion of the acute and subacute period, attempts should be made to wean and discontinue opioid medications as appropriate (i.e., as symptoms improve) and as soon as possible. Dose escalation during these periods should be avoided, as the injury should be stabilized and healing. Medications that are deemed to be inappropriate for the vast majority of injured patients include immediate release, ultra-short acting sublingual and nasal opioid preparations. Long acting opioids are not recommended in the acute and sub-acute phases of treatment. In addition, following major surgical interventions, as acute postoperative pain resolves attempts should be made to wean medications as soon as possible, again avoiding dose escalation beyond the acute post-operative period.

Opioids are not meant to completely eliminate pain, but to ease symptoms and improve function (i.e., improvement of work capacity, ADLs, sleep and sexual function). Any opioids are not meant to completely eliminate pain, but to ease symptoms and improve function or work capacity. At each visit history should be obtained to ensure medications are providing the desired pain reducing effect and looking specifically for side effects such as oversedation, cognitive impairment, or inappropriate medication usage. Any patient maintained beyond a four week period on chronic medications should have appropriate compliance monitoring documented. This should be made through history, screening questionnaires, prescription monitoring programs queries, urine drug tests (up to 2x / yr. for a maintained beyond a four week period must include proper documentation of improvement in pain level (VAS or other screening tool) and improvement in function or work capacity. At each visit history should be obtained to ensure medications are providing the desired pain reducing effect and looking specifically for side effects such as oversedation, cognitive impairment, or inappropriate medication usage. Any patient maintained beyond a four week period on chronic medications should have appropriate compliance monitoring documented. This should be made through history, screening questionnaires, prescription monitoring programs queries, urine drug tests (up to 2x / yr. for a stable, low risk patient and more frequently as indicated for high risk patients), and/or pill counts, as deemed appropriate by the physician. Patients continuing on opioids longer than 4 weeks should be managed under a narcotic agreement as recommended by the Federation of State Medical Boards. Medical necessity should be documented as to the need for all opioid prescriptions in terms of measured improvement in pain, function or work capacity.

If an injured patient requires opioid maintenance longer than 12 weeks, evaluation / consultation and treatment by a physician with appropriate specialty training in pain management should be considered. Documentation of medical necessity, including gains in pain, function or work capacity, is mandatory for prescribing beyond what is described within these guidelines.

The total daily dose of opioids should not be increased or maintained above 90mg oral MED (Morphine Equivalent Dose), unless the patient demonstrates measured improvement in function, pain and/or work capacity. A second opinion from an expert in pain management is recommended, if contemplating raising/maintaining the dose above 90 MED.

Before prescribing opioids for chronic pain, potential comorbidities should be evaluated. These include opioid addiction, drug or alcohol problems and depression. A baseline urine test for drugs of abuse and assessment of function and pain should be performed prior to institution of opioids for chronic pain.

GUIDELINES FOR PRESCRIBING

Connecticut law limits initial prescriptions to a 7-day supply for adults; exceptions are allowed for patients with chronic pain or acute pain that will last beyond 7 days with appropriate chart documentation.

Associated risks of addiction and overdose must be explained to the patient before prescribing controlled substances for the first time.

State law requires the PDMP be checked prior to the first prescription.

Single prescriber
Single pharmacy
Opioid agreement

Caution should be used with:

- combination therapy
- sedative-hypnotics
- muscle relaxants
- benzodiazepines

Routine assessment of pain and function, if there is no improvement

Weaning of opioid

General:

- Whenever a prescribing practitioner prescribes controlled substances for the continuous or prolonged treatment of any patient, such prescriber, or such prescriber’s authorized agent who is also a licensed health care professional, shall review, not less than once every ninety (90) days, the patient’s records in the Connecticut Prescription Monitoring and Reporting System (CPMRS) at www.ctpmp.com

Oxymorphone

Hydrocodone
- 1
Methadone up to 20mg
- 4
Methadone 21-40mg
- 8
Methadone 41-60mg
- 10
Methadone >60mg
- 12
Morphine
- 1
Methadone 0.15

Opioid therapy produces significant adverse effects, or

Patient exhibits drug-seeking behaviors or diversions such as:

- selling prescription drugs
- forging prescriptions
- stealing or borrowing drugs
- frequently losing prescriptions
- aggressive demand for opioids
- injecting oral / topical opioids
- unsanctioned use of opioids
- unsanctioned dose escalation
- concurrent use of illicit drugs
- failing a drug screen
- getting opioids from multiple prescribers
- recurring emergency department visits for chronic pain management

If there is no measured improvement in pain, function, ADLs or work capacity after three (3) months of opioid medication, the prescribing physician must justify the continued use of opioids and should consider weaning of the opioid.

Opioids may allow the patient to return to work safely and more expeditiously and therefore may be indicated; nevertheless, attempts to wean these medications and avoidance of dose escalation should be the goal of treatment.

This document is meant as a guideline for the practitioner and should not supplant proper medical judgment.

REASONS TO DISCONTINUE OPIOIDS OR REFER FOR ADDICTION MANAGEMENT

</table>
Use of chronic controlled substances in chronic pain management is acceptable in appropriate clinical situations. However, there are a number of risks associated with these medications, which have been well documented and include addiction, overdose, and death. Careful monitoring is required to maximize safety when prescribing opioid medications.

In addition to other risks, opioid medications can also interact with many medications, including:
- other prescribed controlled substances (i.e., benzodiazepines)
- anti-depressants
- medical marijuana
- other common medications

Prescribing providers must ensure the safe use of this form of potentially risky medical treatment, including its interaction with other prescribed medications.

Chronic opioid management requires careful, ongoing monitoring to ensure that each patient complies with directions given for the proper use of all prescribed medications. Such monitoring provides objective information that can help identify the presence or absence of drugs or drug classes in the body, assisting clinicians in making appropriate treatment decisions for patients requiring chronic controlled substances as part of their medical care.

In addition, each patient must be screened to assess his or her risk status (see “PATIENT RISK ASSESSMENT” on page 5 of these Opioid Protocols), by means of:
- a full medical and personal history
- administration of a risk assessment interview or questionnaire
- review of any documented evidence that may exist of any type of aberrant behavior known to indicate a potentially increased risk to the patient, if chronic opioid management is utilized as part of that patient’s treatment plan

NOTE: the Commission’s previously-published opioid guidelines encourage clinicians to avoid high-dose long-term prescribing, given the lack of medical evidence supporting such practice.

### ROUTINE DRUG TESTING

Routine testing of patients:
- is “best practice” when providing pain management and opioid therapy – such testing can help to identify:
  - drugs of adherence
  - drugs of abuse
- may detect the presence of prescribed medication, helping to:
  - verify patient compliance
  - reinforce therapeutic compliance
  - provide documentation demonstrating compliance
- may detect the absence of prescribed medication, indicating possible:
  - non-compliance
  - abuse
  - misuse
  - diversion
- may detect the use of substances that could result in:
  - adverse events
  - drug-drug interactions
- may detect the use of undisclosed substances:
  - alcohol
  - unsanctioned prescription medications
  - illicit substances

### FREQUENCY OF TESTING

It is neither medically indicated, nor appropriate, to test every single patient at every single visit. To ensure patient compliance, the Connecticut workers’ compensation system considers the medically appropriate to randomly perform Point-of-Care (POC) urine drug testing (UDT) for patients receiving chronic opioid treatment:
- 2x/year (minimum)
- up to 4x/year (maximum)
- more frequently (if medical indications dictate)

Additional testing – above and beyond 4x/year – will only be covered for specific, documented medical indications, including:
- following up on abnormal urine drug test results (to confirm patient compliance)
- an aberrant PMP report
- a patient at high risk for abuse
- a patient with a known history of substance abuse (based on an “outside” report of potential abuse, i.e., from the carrier, another physician, a family member, or other source)

Medical indications requiring more frequent testing must be documented in the patient’s medical records.

### DRUG TESTS — DEFINED

#### Point-of-Care (POC) Drug Testing
- qualitative testing which provides immediate results
- used when medically necessary by clinicians for immediate patient management
- available when the patient and physician are in the same location
- testing is performed by office staff
- read by the human eye
- immunoassay (IA) test method that primarily identifies drug classes and a few specific drugs
- platform consists of cups, dipsticks, cassettes, or strips
- limited accuracy, requiring confirmatory testing for unexpected or unexplained results

#### Qualitative Drug Testing
- when medically necessary, determines presence or absence of drugs or drug classes in urine sample
- results expressed as negative, positive, or as a numerical result
- includes competitive immunoassays (IA) and thin layer chromatography
- performed by licensed laboratorian (MT / MLT- ASCP)

#### Definitive / Quantitative / Confirmation
- used when medically necessary to identify specific medications, illicit substances, and metabolites
- reports the results of drugs absent or present in concentrations of ng/ml
- limited to GC-MS and LC-MS / MS testing methods only
- performed by licensed laboratorian (MT / MLT- ASCP)

#### Specimen Validity Testing
- ensures urine specimen is consistent with normal human urine and has not been adulterated or substituted
- may include pH, specific gravity, oxidants, temperature, and creatinine

#### Immunoassay (IA)
- qualitative / semi-quantitative testing
- ordered by clinicians primarily to identify presence or absence of drug classes and some specific drugs
- biochemical test to measure the presence of a substance (drug) — above a cutoff level — using an antibody
- read by photometric technology
- chemistry analyzers with IA UDT technology are used in office and clinical laboratory settings
- may be used when less immediate test results are required
- at no time is IA technology by chemistry analyzer analysis considered confirmatory testing
- performed by licensed laboratorian (MT / MLT- ASCP)
### Point-of-Care (POC) Drug Testing

Point-of-Care (POC) or “in-office” (enzyme immunoassay) drug testing is that which is done in the office using any number of types of immunoassay testing.

POC testing should be the primary route of routine urine drug screening, and is encouraged, because:

- It has the advantage of providing the clinician with immediate feedback
- It assists the clinician in making appropriate clinical decisions at the same time that a prescription is provided

Basic POC dip stick / cup / card / cartridge testing is expressly allowed under these protocols.

Initial testing should be with basic immunoassay drug panels (usually 10-12 drugs).

Confirmatory testing should only be performed as described in “Confirmatory Drug Testing” on page 4 of these Opioid Protocols.

### Testing Facilities – Labs

Physician Office Labs (POLs) must meet all of the same standards as those that third-party labs must meet.

Some offices, however, are not equipped to perform routine POC urine drug testing.

Offices not equipped to perform such testing themselves may send their patients to outside testing labs, which can typically be found at:

- Outpatient facilities
- Hospitals

### Urine Drug Testing (UDT)

Urine Drug Testing (UDT) is an important component of proper medical monitoring for patients on chronic controlled substances, along with:

- Review of data in Connecticut’s Prescription Drug Monitoring Program (CT PDMP)
- Pill counts
- Narcotic / opioid agreements

UDT provides objective information that can help identify the presence or absence of drugs or drug classes in the body, assisting clinicians in making appropriate treatment decisions for patients requiring chronic controlled substances as part of their medical care.

Baseline UDT (typically POC testing) should be performed – and documented in the medical record:

- When the clinician decides that medications are to be prescribed to a workers’ compensation patient with chronic pain, on a long-term basis, for the management of that patient’s pain symptoms
- Or
- When a patient enters into a new practice with a change of providers

Thereafter, UDT should be used for monitoring patients according to the guidelines listed in “Frequency of Testing” on page 2 of these Opioid Protocols:

- Periodically and randomly
- Or
- Non-randomly, when indicated for other medical reasons

Urine drug tests that are abnormal may be sent for confirmation (quantitative analysis) to an outside laboratory, for either:

- Not showing the appropriate medications that the patient is supposed to be taking
- Or
- Showing medications that the patient is not supposed to be taking

### UDT – Billing and Payment

The reimbursement for this service is set within the Official Connecticut Practitioner Fee Schedule.

No pass-through / indirect billing will be allowed for UDT confirmation or quantitative testing.

Each physician’s office location that performs point-of-care drug screen testing is required to have the necessary CLIA certification.

In-office immunoassay testing is only considered to be a qualitative test (by all standards) and is not considered to be a quantitative test.
### Confirmatory Drug Testing

<table>
<thead>
<tr>
<th>Abnormal Urine Drug Tests</th>
<th>Confirmatory Drug Testing</th>
<th>Quantitative Analysis and Semi-Quantitative Testing</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>UDTs should be sent for confirmation for all new patients (first-time visit) and:</strong></td>
<td>When confirmatory testing is requested, the clinician must document the rationale supporting the definitive UDT, and all tests ordered must be documented in the patient’s medical record as well.</td>
<td></td>
</tr>
<tr>
<td>- when there are inconsistencies in UDT with prescribed medications</td>
<td>Confirmatory testing is only required – and should be performed – when:</td>
<td></td>
</tr>
<tr>
<td>- to confirm that the patient is taking all the medications on their list</td>
<td>- the validity of the POC in-office test is in question</td>
<td></td>
</tr>
<tr>
<td>- to check for illicit medications (all patients with moderate or high risk)</td>
<td>- the results of the POC in-office test need to be confirmed</td>
<td></td>
</tr>
<tr>
<td>- when a prescribed medication is not included in standard POC testing (documentation of the specific reason for confirming specific medications for each patient should be contained within the medical record)</td>
<td>- a prescribed medication is not included in standard POC testing</td>
<td></td>
</tr>
</tbody>
</table>

Therefore, confirmatory UDT is reasonable and necessary to definitively:

- rule out error as causing an unexpected presumptive UDT result
- identify a negative – or confirm a positive – presumptive UDT screen inconsistent with a patient’s:
  - self-report
  - medical history
  - presentation of symptoms
  - current prescribed pain medication plan
- identify specific substances / metabolites inadequately detected by a presumptive UDT screen
- identify specific substances / metabolites undetected by a presumptive UDT screen:
  - fentanyl – synthetic cannabinoids
  - meperidine – other synthetic / analog drugs
  - tramadol
- identify specific drugs within drug classes in a large family of drugs
- identify non-prescribed medication – or illicit use – for ongoing safe prescribing of CONTROLLED substances

The combination of these tests can help identify and quantify each specific drug and / or its metabolite.

Quantitative testing is relative, affected by many factors, and should not be used to guide dosage of medication.

Since an immunoassay and an enzyme assay are by definition moderately complex tests that produce qualitative and semi-quantitative results, they may not be reported with a quantitative code.

---

**Note:** The highest level in any category defines level of risk.

- **Low risk:** 
  - 2x / 12 months
  - moderate risk: 1-2x / 6 months
  - high risk: 1-3x / 3 months

- **Moderate risk:** 
  - 50-90 mg. MEQ, ORT = 4-7

- **High risk:** 
  - > 90 mg. MEQ, ORT ≥ 8

**Documentation should also include an action plan designed to address any abnormal UDT results – such plan may include:**

- confirmatory drug testing
  - abnormal UDTs may be sent to an outside laboratory for confirmatory testing (quantitative analysis)
- more frequent UDTs
- more frequent visits for monitoring
- discontinuation of medications
- change to non-addictive medications
- prescriptions for shorter periods of time:
  - only 1-2 weeks of medications
- additional testing, such as:
  - pill counts
  - frequent checks of Connecticut’s Prescription Drug Monitoring Program (CT PDMP)

**UDTs should be stratified by frequency for UDT testing:**

- Confirmatory testing of that particular medication is not indicated
- Confirmatory testing of other medications may still be indicated

**POC UDT should not automatically and routinely be sent for outside confirmation of large panels of multiple medications:**

- suspected of being abnormal in POC testing
- shown to be abnormal in POC testing
- suspected of being drugs of abuse
DRUG TESTING OF HIGHER-RISK PATIENTS

PATIENT RISK ASSESSMENT

Before including controlled substances in patients’ pain management treatment plans, clinicians should assess them for potential risks to which they may be susceptible.

Patient risk assessment is performed by:

- taking the patient’s full medical and personal history, including:
  - a full accounting of any previously-prescribed medications
  - a history of substance abuse
  - a history of substance misuse
- administering a risk assessment interview or questionnaire:
  - Opioid Risk Tool (ORT)
  - Screener and Opioid Assessment for Patients with Pain (SOAPP)
  - other form of written test
- reviewing any existing documentation containing evidence of any type of aberrant behavior known to indicate a potentially increased risk to the patient (if chronic opioid management is utilized as part of that patient’s treatment plan)
- classifying the patient according to the Risk Group Stratification chart at the right

Each patient’s risk assessment must be documented in his or her medical record.

FREQUENCY OF TESTING

Moderate and high-risk patients require more frequent monitoring and additional oversight to ensure compliance with their medication management.

Moderate and high-risk groups should receive more frequent UDT than low-risk patients:
- at least every 3-4 months
- 2x/year

In high-risk patients, additional testing may be periodically indicated, if the clinician has a high suspicion and can document the need for more extensive confirmatory testing (including drugs that may not be tested on a basic POC screen).

Psychiatric co-morbidity may increase risk stratification and be an indication for more frequent testing (and lower-dose therapy).

More frequent testing may be indicated following abnormal test results in high-risk patients.

RISK GROUP STRATIFICATION

Risk Group Stratification can be categorized according to 3 different criteria:

- Opioid Risk Tool (ORT) / SOAPP / other form of written test
- Morphine Equivalent Dosage (MEQ or MED)
  and/or
- prior aberrant behavior

While increased practitioner vigilance is appropriate, not all patients in these categories – based on ORT / SOAPP or MEQ / MED – will ultimately go on to demonstrate aberrant behavior.

<table>
<thead>
<tr>
<th>RISK GROUP</th>
<th>ORT Score / SOAPP Score</th>
<th>MEQ / MED *</th>
<th>ABERRANT BEHAVIOR</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low</td>
<td>0 – 3 / &lt; 7</td>
<td>&lt; 50</td>
<td>No</td>
</tr>
<tr>
<td>Moderate</td>
<td>4 – 7 / ≥ 7</td>
<td>50 – 90</td>
<td>No</td>
</tr>
<tr>
<td>High</td>
<td>≥ 8 / ≥ 7</td>
<td>&gt; 90</td>
<td>Yes</td>
</tr>
</tbody>
</table>

Suspicious behaviors, including:
- self-escalation of dose
- doctor-shopping, with documentation on Connecticut’s Prescription Drug Monitoring Program (CT PDMP)
- indications / symptoms of illegal drug use
- evidence of diversion
- other documented misuse or abuse
  or
- a notable change in affect or behavior pattern

* MEQ / MED = daily dosage for patient (in morphine equivalents)
### Neck Pain History and Physical Examination

**MEDICAL PROTOCOLS: CERVICAL SPINE – PAGE 2 of 9**
**SUBACUTE AXIAL NECK INJURY (1-3 MONTHS)**

### DIAGONSTIC CRITERIA

- **On initial visit:**
  - complete history
  - physical examination
  - pain diagram

- **Height and weight (BMI)**

- **On each visit document:**
  - primary diagnosis
  - precise location and character of pain
  - VAS pain level
  - current meds
  - exam pertinent to injured body part
  - functional capacity
  - appraisal of ADLs and functional activity

- **Work capacity and status**

- **Appraise compliance**

- **Consider specialty referral, if not improving**

### DIAGNOSTIC STUDIES

**Recommended:**
- X-Ray, especially if previous injury or surgery
- MRI after 6 weeks, if clinically indicated

**Not Recommended:**
- CT Scan
- Discogram

### TREATMENT

**Chiropractic or Physical Therapy:**
- no isolated passive modalities (hot pack / cold pack, ultrasound, electrical stimulation)
- exercise
- strengthening
- core
- aerobic
- assess and document progress
- up to 12 additional visits based on measured improvement in VAS, function and work capacity

- **Assess BMI and smoking and counsel appropriately**

**Medications:**
- NSAIDs
- acetaminophen
- opioid – see opioid protocol
- antidepressants
- muscle relaxants

**Injections:**
- see IPM Protocol

**Limited Indication:**
- anticonvulsants

### GOALS OF TREATMENT

**Recommend RTW:**
- sedentary ....................... 0-3 days
- light-med ..................... 7-17 days
- heavy .......................... 14-35 days

**Contingent on assessment of functional capacity**

### IF GOALS NOT MET

- **Consider alternative cause**

- **Consider psychological factors**
  - see Psychological Guideline

- **Administer standard psych assessment tool such as ODI**
# CHRONIC AXIAL NECK INJURY (GREATER THAN 3 MONTHS)

## GOALS OF TREATMENT

- Recommend RTW:
  - sedentary.................0-3 days
  - light-med..................7-17 days
  - heavy .....................14-35 days

Contingent on assessment of functional capacity

## IF GOALS NOT MET

- Consider alternative cause
- Consider psychological factors
  - see Psychological Guideline
- Administer standard psych assessment tool such as ODI
- Consider time limited behavioral cognitive therapy
- Functional capacity evaluation / vocational rehab
- Change of job
- Surgery may be considered for appropriate cases
  - see Surgery page

## MEDICATIONS

- NSAIDs
- acetaminophen
- opioid – see Opioid Protocol
- antidepressants
- muscle relaxants

## INJECTIONS

- see IPM Guideline

## NOT RECOMMENDED

- bed rest
- anticonvulsants
### Diagnostic Criteria

- Complete history
- Physical exam
- Pain diagram
- Height and weight (BMI)

On each visit document:
- Primary diagnosis
- Precise location and character of pain
- Accurate description of weakness, sensory and reflex abnormalities
- Root tension signs
- VAS pain level and/or leg on each visit
- Functional capacity
- Appraisal of ADLs and functional activity
- Work capacity and status

### Diagnostic Studies

**Recommended:**
- No X-Rays (unless indicated by amount of trauma or based on documented medical suspicion)
- MRI or CT myelogram for progressive neurological deficit

**Not Recommended:**
- CT Scan (unless indicated by degree of trauma)
- Discogram

### Treatment

**Recommended:**
- Chiropractic or Physical Therapy:
  - Encourage increased activity ASAP
  - Education
  - Active treatment strengthening and aerobic, as tolerated
  - Passive modalities up to 2 weeks (hot pack/cold pack, ultrasound, electrical stimulation)
  - Traction
- Up to 12 visits
  - Document functional and VAS improvement to continue after 8 visits

**Medications:**
- NSAIDs
- Steroids, if severe
- Muscle relaxants – 2 weeks
- Opioid – see Opioid Protocol
- Anticonvulsants
- Antidepressants
- Acetaminophen

**Injections:**
- See Injection Guideline

**Follow-up:**
- Within 2 weeks

**Not Recommended:**
- Bed rest

### Goals of Treatment

**Recommend RTW:**
- Sedentary.......................... 0-3 days
- Light-med......................... 7-17 days
- Heavy............................... 14-35 days

Contingent on assessment of functional capacity

### If Goals Not Met

**Document:**
- Compliance
- No shows/cancellations
- Effort: clinic
- Effort: home
## Subacute Cervical Radiculopathy (1-3 Months)

### Diagnostic Criteria

- On initial visit:
  - complete history
  - physical exam
  - pain diagram
  - Height and weight (BMI)

- On each visit document:
  - primary diagnosis
  - precise location and character of pain
  - accurate description of weakness, sensory and reflex abnormalities
  - root tension signs
  - VAS Pain level and/or leg on each visit
  - functional capacity
  - appraisal of ADLs and functional activity

- Current meds
- Work capacity and status
- Appraise compliance
- Consider specialty referral, if not improving

### Diagnostic Studies

**Recommended:**
- X-Ray (especially if previous injury or surgery)
- MRI
- consider CT Scan to evaluate bony anatomy for foraminal stenosis
- EMG (needle) with neurological signs and symptoms and equivocal MRI or CT findings

**Not Recommended:**
- Discogram

### Treatment

**Recommended:**
- Chiropractic or Physical Therapy:
  - no isolated passive modalities (hot pack/cold pack, ultrasound, electrical stimulation)
  - exercise, strengthening, core, aerobic (assess and document progress)
  - additional visits based on measured improvement in VAS, functional and work capacity
  - assess BMI and smoking and counsel appropriately

- Medications:
  - NSAIDS
  - antidepressants
  - anticonvulsants
  - acetaminophen
  - opioid – see Opioid Protocol

- Injections:
  - see IPM Guideline

- Follow-up:
  - within 3 weeks

**Not Recommended:**
- bed rest

### Goals of Treatment

**Recommend RTW:**
- sedentary....................... 0-3 days
- light-med...................... 7-17 days
- heavy ......................... 14-35 days

Contingent on assessment of functional capacity

### If Goals Not Met

- Document compliance
- Consider psychological factors
  - see Psychological Guideline
- Administer standard psych assessment tool (such as ODI)
- Consider surgery for compressive radiculopathy
### CHRONIC CERVICAL RADICULOPATHY (GREATER THAN 3 MONTHS)

#### DIAGNOSTIC CRITERIA

- On initial visit:
  - complete history
  - physical exam
  - pain diagram

- Height and weight (BMI)

- On each visit document:
  - primary diagnosis
  - precise location and character of pain
  - accurate description of weakness, sensory and reflex abnormalities
  - root tension signs
  - VAS pain level and / or leg on each visit
  - functional capacity
  - appraisal of ADLs and functional activity

- Current meds
- Work capacity and status
- Appraise compliance
- Consider specialty referral, if not improving

#### DIAGNOSTIC STUDIES

- Recommended:
  - X-Ray (especially if previous injury or surgery)
  - MRI

- Consider CT Scan to evaluate bony anatomy for foraminal stenosis

- EMG (needle) with neurological signs and symptoms and equivocal MRI or CT findings

#### TREATMENT

- Recommended:
  - Chiropractic or Physical Therapy:
    - no passive modalities, unless acute flare-up (hot pack / cold pack, ultrasound, electrical stimulation)
    - exercise, strengthening, core, aerobic (assess and document progress)
    - assess BMI and smoking and counsel appropriately
    - weight reduction for BMI > 30

- Medications:
  - NSAIDs
  - antidepressants
  - anticonvulsants
  - acetaminophen
  - opioid – see Opioid Protocol

- Injections:
  - see IPM Guideline

- Surgery:
  - if documented compression

- Not Recommended:
  - bed rest

#### GOALS OF TREATMENT

- Recommend RTW:
  - sedentary ....................... 0-3 days
  - light-med ...................... 7-17 days
  - heavy ........................ 14-35 days

  Contingent on assessment of functional capacity

#### IF GOALS NOT MET

- EMG to document neurological status
- Consider psychological factors
- see Psychological Guideline
- Administer standard psych assessment tool (such as ODI)
- Consider time-limited behavioral cognitive therapy
- Functional capacity evaluation / vocational rehab
- Functional restoration program
- Spinal cord stimulation:
  - neurological pain > 6 months
  - adequate psychological evaluation prior to SCS trial
  - see psychological guideline

Medical protocols for cervical spine – Page 9 of 9

Interventional pain management: Basic guidelines for axial neck pain

- Medical necessity for all injections must be documented with a clear description of the diagnosis and rationale for the injection.
- Injured workers should be re-evaluated @ 2 weeks following any intervention to assess change in pain level, change in function (and hence work status), and to determine next steps in the treatment course if medically indicated. IPM treatments (‘blocks’) are generally not a treatment performed in isolation; it is important to look at the underlying cause and include functional based exercise programs along with injections.
- Frequently cervical injuries are simply myofascial strains that can be relieved with PT and stretching. Trigger point injections may be used to facilitate and speed the recovery process if the injured worker is not progressing with conservative management alone or if it is felt that early intervention will speed return to normal work activities.
- All spinal injections must be performed with radiologic guidance, typically fluoroscopy is utilized. CT guided pain management injections should only be performed for specific indications and medical necessity must be documented. Ultrasound is a form of radiologic guidance being used for many different pain injections but cannot be recommended for spinal injections at this time.
- All spinal injections should be accompanied with a report of both the diagnostic and therapeutic response. An injection that does not provide relief still provides diagnostic information as to what is not the cause of the pain. A lack of response to a particular intervention still provides useful information and that should be duly noted in the records. This will prevent further unnecessary injections for pain generating structures that have been found to not be the cause of pain.
- For injured workers who fail to respond to treatment, alternative diagnoses should be considered. If the worker fails to respond to treatment that appears to be appropriate for the condition, evaluation of other barriers to improvement such as psychological issues should be considered.
- Cervical facet blocks are indicated for the diagnosis and treatment of neck pain with or without pseudoradiculal symptoms for pain that is suspected of arising from the facet joints. A history and physical examination should document the clinician’s rationale for this suspected diagnosis. Definitive diagnosis requires documenting the patient’s response to a diagnostic injection.
- Therapeutic facet blocks will only be considered as proper management when they provide at least 70% relief of the cervical symptoms and at least 3 months of pain relief and will be limited to a maximum of 3 sets of therapeutic facet injections/year. All facet injections should include steroid (unless otherwise contraindicated) in hopes of providing long term therapeutic effect and to improve the diagnostic specificity of these injections. Patients obtaining only short term relief (less than 3 months) should be considered for more long lasting solutions, such as RF ablation. Some patients can be managed with intermittent therapeutic facet injections.
- Repeat therapeutic injections/procedures are only indicated for those individuals who document sustained improvement in both pain and function, including improved ADL’s and functional capacities for at least three months.
- In addition, if the patient has significant bilateral pain, bilateral injections should be performed with the diagnostic injection so the clinician can better and more fully assess the etiology of the pain. Residual pain from joints that are not treated will confuse the diagnostic information that is obtained from a diagnostic block.
- Radiofrequency ablation (Facet rhizotomy) may be considered for patients who achieve short-term relief with at least 70% reduction of target symptoms along with improved function and ROM with a diagnostic injection (Note-face blocks are not expected to result in improvement of radicular symptoms). Radiofrequency ablation requires that the patient has had a facet medial branch mapping procedure, intra-articular injections are not diagnostic for determining the need for RF. Rhizotomy cannot be performed more frequently than once every 6 months.
- If there is a question about the etiology of recurrent pain, re-evaluation and repeat diagnostic workup should be considered prior to repeat injections.
- Epidural steroid injections may be indicated for axial neck pain that is felt to be radicular or discogenic in origin and for which there is a specific possible spinal cause. A diagnosis of discogenic pain is often a diagnosis of exclusion and other causes of neck pain should be evaluated before considering ESI’s for treatment of axial pain. Epidural steroid injections may not be performed without an MRI documenting the specific location and extent of spinal pathology, for both safety and accuracy reasons. The routine performance of three epidural steroid injections is not appropriate and results in unnecessary treatment. After each injection, the response should be documented both for pain and functional improvement; if a repeat injection is required medical necessity should be documented even if a series of injections has been approved.
- Pain can arise out of multiple structures and therefore can be multifactorial in origin, nevertheless it is not expected that every single injured worker with a cervical injury will require every single different type of injection, and in fact such practice is not recommended and is strongly discouraged.

Interventional pain management: Therapies for cervical radiculopathy

- Epidural Steroid Injections (ESI) are indicated for the treatment of a radiculopathy/ radiculitis with symptoms of pain in a radicular distribution, which can be associated with numbness, tingling, and/or weakness in that nerve root distribution. A lack of response should lead the clinician to reconsider the diagnosis or look for alternative treatment options. Medical necessity for all injections must be documented with a clear description of the symptoms, physical findings, diagnosis and rationale for the injection.
- Injured workers should be re-evaluated @ 2 weeks following any intervention to assess change in pain level, change in function (and hence work status), and to determine next steps in the treatment course if medically indicated. IPM treatments (‘blocks’) are generally not a treatment performed in isolation; it is important to look at the underlying cause and include functional based exercise programs along with injections.
- All spinal injections should be accompanied with a report of both the diagnostic and therapeutic response. An injection that does not provide relief still provides diagnostic information as to what is not the cause of the pain. This will prevent further unnecessary injections for structures that have been found not to be the cause of pain.
- Earlier intervention with an ESI may help to speed recovery and promote progress in PT and therefore should be considered in the management of an acute radiculopathy that is not responding to conservative management.
- Epidural steroid injections may not be performed without an MRI documenting the specific location and extent of spinal pathology and should be correlated with neurologic findings.
- Delivery of medication to the location of nerve irritation is the key to success. Injections require radiologic guidance for accuracy and safety. All spinal injections must be performed with radiologic guidance, typically fluoroscopy. CT guided pain management injections should only be performed for specific indications and medical necessity must be documented. Ultrasound is not recommended for spinal injections at this time.
- There are several different approaches to the epidural space but delivery of medication as close as possible to the target location is helpful to optimize outcomes. The choice between interlaminar, transforminal, and catheter guided approaches will be left to the clinician but the risks and benefits of the various approaches should be carefully considered when deciding technique.
- The routine performance of three epidural steroid injections is not appropriate and results in unnecessary treatment. After each injection, the response should be documented both for pain and functional improvement; if a repeat injection is required medical necessity must be documented.
- Injured Workers who do not respond with sustained benefit should be considered for definitive decompression of the involved nerve root(s).
### Low Back Pain History and Physical Examination

#### History of Present Illness
- Description of Injury:
  - details of events before, during, and immediately after the alleged injury
  - mechanism of injury
  - identification of body parts involved
  - location of the pain, characteristics of the pain, and distribution of the pain symptoms
  - frequency and duration of symptoms
  - alleviating / exacerbating factors

- Any limitations in functional activities should be noted.

The history should include the presence and distribution of any lower extremity numbness, paresthesias, or weakness and a description as to whether or not it is precipitated or worsened by coughing or sneezing.

Any changes in bowel, bladder, or sexual function should be identified, as they may indicate a more severe spinal injury. The presence of a serious or progressive neurological deficit demands immediate attention and appropriate triage.

The possibility of low back pain from other non-traumatic sources should be investigated by asking questions about fever, rash, swelling, unexplained weight loss, morning stiffness, etc.

A visual analog pain scale should be used and monitored at each visit. The patient should be asked their current rating, average over the last week and range from low to high.

Note any history of emotional and/or psychological response to the current injury.

#### Medications
- History should include:
  - previous medications taken for this back injury
  - a list of all current medications, including dose and frequency
  - any significant side effects from previous medications

Identify any previous occupational and non-occupational injuries to the same area.

Determine if the patient has any history of non-traumatic back problems such as arthritis, cancer, surgery, etc.

Document any prior back treatment, chronic or recurrent symptoms, response to previous treatment, and any functional limitations or previous restrictions in work capacity.

Demographic screening to identify:
  - any previous psychological diagnosis/treatment including psychiatric hospitalization, outpatient psychotherapy/counseling, or psychopharmacological treatment (e.g. antidepressants, anxiolytics, etc.)
  - diagnosis and/or treatment of any drug or alcohol abuse or dependence (e.g. life interference such as relationships, work, DWI, detoxifications, inpatient/oupatient rehabilitation or 12-step participation)
  - prior treatment for work-related pain
  - prior workers’ compensation claim with pain-related lost time

#### Allergies
- Medication allergies should be verified at every visit.

Identify systemic disease symptoms:
  - cardiac
  - endocrine
  - gastrointestinal
  - hematological
  - infectious
  - neurologic
  - neoplastic
  - renal
  - rheumatologic
  - other

#### Social History
- Identify:
  - smoking
  - alcohol use
  - other drug use
  - vocational activities
  - recreational activities

#### Review of Systems
- Identify systemic disease symptoms:
  - cardiac
  - endocrine
  - gastrointestinal
  - hematological
  - infectious
  - neurologic
  - neoplastic
  - renal
  - rheumatologic
  - other

#### Physical Examination
- Physical examination:
  - vital signs
  - general appearance, including posture
  - height
  - weight
  - any pain behaviors

Signs of symptom amplification should be noted.

Visual inspection of back

Palpation of lumbar spine including:
  - midline
  - paraspinal and posterior elements
  - sacroiliac regions
  - hips
  - gluteal regions

Make a note of:
  - range of motion
  - quality of motion
  - nerve tension testing, both single leg and crossed leg
  - exacerbating or alleviating motions
  - deep tendon reflexes

Sacroiliac and piriformis testing should be considered.

Sensory and motor examination of the lower extremities with specific description of abnormalities.

Assessment of transfers and gait

In cases where the mechanism of injury, history, or clinical presentation suggests a possible severe injury, additional evaluation is indicated.

A detailed neurological examination for possible spinal cord injury should include:
  - sharp and light touch, deep pressure, temperature, and proprioceptive sensory function
  - anal sphincter tone and/or perianal sensation
# Acute Axial Back Injury (Less Than 4 Weeks)

## Diagnostic Criteria

On initial visit:
- complete history
- physical examination
- pain diagram

Height and weight (BMI)

On each visit document:
- primary diagnosis
- precise location and character of pain
- VAS pain level
- exam pertinent to injured body part
- functional capacity
- appraisal of ADLs and functional activity

Work capacity and status

## Diagnostic Studies

Recommended:
- no X-Rays (unless indicated by amount of trauma or based on documented medical suspicion)
- MRI or CT myelogram for progressive neurological deficit

## Treatment

Recommended:
- Chiropractic or Physical Therapy:
  - encourage increased activity ASAP
  - education
  - active treatment strengthening and aerobic, as tolerated
  - passive modalities up to 2 weeks (hot pack / cold pack, ultrasound, electrical stimulation)

  - Up to 12 visits
  - document functional and VAS improvement to continue after 8 visits

Medications:
- NSAIDs
- acetaminophen
- muscle relaxants
- opioid – see Opioid Protocol

Injections:
- see IPM Protocol

Follow-up:
- 1 week, if work modified
- 4 weeks, if no work modification

Not recommended:
- bed rest

## Goals of Treatment

Recommend RTW:
- sedentary ....................... 0-3 days
- light-med ...................... 7-17 days
- heavy ......................... 14-35 days

Contingent on assessment of functional capacity

## If Goals Not Met

Document:
- compliance
- no shows / cancellations
- effort: clinic
- effort: home

Consider oral steroids for severe pain

# Acute Lumbar Radiculopathy (Less than 4 Weeks)

## Diagnostic Criteria

**On initial visit:**
- complete history
- physical exam
- pain diagram

*Height and weight (BMI)*

**On each visit document:**
- primary diagnosis
- precise location and character of pain
- accurate description of weakness, sensory and reflex abnormalities
- root tension signs
- VAS pain level and / or leg on each visit
- functional capacity
- appraisal of ADLs and functional activity

*Work capacity and status*

## Diagnostic Studies

**Recommended:**
- no X-Rays (unless indicated by amount of trauma or based on documented medical suspicion)
- MRI or CT myelogram for progressive neurological deficit

**Not Recommended:**
- Discogram

## Treatment

**Recommended:**
- Chiropractic or Physical Therapy:
  - encourage increased activity ASAP
  - education
  - active treatment strengthening and aerobic, as tolerated
  - passive modalities up to 2 weeks (hot pack / cold pack, ultrasound, electrical stimulation)
  - traction
  - Up to 12 visits
  - document functional and VAS improvement to continue after 8 visits

**Medications:**
- NSAIDs
- acetaminophen
- muscle relaxants – 2 weeks
- opioids – see Opioid Protocol
- anticonvulsants
- antidepressants
- oral steroids

**Injections:**
- see Injection Guideline

**Follow-up:**
- 2 weeks

**Not Recommended:**
- bed rest

## Goals of Treatment

**Recommend RTW:**
- sedentary....................... 0-3 days
- light-med..................... 7-17 days
- heavy ......................... 14-35 days

*Contingent on assessment of functional capacity*

## If Goals Not Met

**Document:**
- compliance
- no shows / cancellations
- effort: clinic
- effort: home

*Consider oral steroids for severe pain*

## Medical Protocols:

**RECOMMENDED:**
- X-Ray (especially if previous injury or surgery)
- MRI
- Consider CT Scan to evaluate bony anatomy for foraminal stenosis
- EMG (needle) with neurological signs and symptoms and equivocal MRI or CT findings

**NOT RECOMMENDED:**
- Discogram

**TREATMENT**
- Chiropractic or Physical Therapy:
  - no isolated passive modalities (hot pack / cold pack, ultrasound, electrical stimulation)
  - exercise, strengthening, core, aerobic (assess and document progress)
  - additional visits based on measured improvement in VAS, functional and work capacity
  - assess BMI and smoking and counsel appropriately
- **Medications:**
  - NSAIDS
  - acetaminophen
  - opioid – see Opioid Protocol
  - antidepressants
  - anticonvulsants
- **Injections:**
  - see IPM Guideline
- **Follow-up:**
  - within 3 weeks

**GOALS OF TREATMENT**
- **Not Recommended:**
  - bed rest
### CHRONIC LUMBAR RADICULOPATHY (GREATER THAN 3 MONTHS)

#### DIAGNOSTIC CRITERIA

**On initial visit:**
- complete history
- physical exam
- pain diagram

**Height and weight (BMI)**

**On each visit document:**
- primary diagnosis
- precise location and character of pain
- accurate description of weakness, sensory and reflex abnormalities
- root tension signs
- VAS pain level and / or leg on each visit
- functional capacity
- appraisal of ADLs and functional activity

**Current meds**

**Work capacity and status**

**Appraise compliance**

**Consider specialty referral, if not improving**

#### DIAGNOSTIC STUDIES

**Recommended:**
- X-Ray (especially if previous injury or surgery)
- MRI

**Consider CT Scan** to evaluate bony anatomy (e.g., spondylolisthesis)

**EMG (needle)** with neurological signs and symptoms and equivocal MRI or CT findings

#### TREATMENT

**Recommended:**
- Chiropractic or Physical Therapy:
  - no passive modalities, unless acute flare-up (hot pack / cold pack, ultrasound, electrical stimulation)
  - exercise, strengthening, core, aerobic (assess and document progress)
  - additional visits based on measured improvement in VAS, functional and work capacity
  - assess BMI and smoking and counsel appropriately
  - weight reduction for BMI > 30

**Medications:**
- NSAIDS
- acetaminophen
- opioid – see Opioid Protocol
- antidepressants
- anticonvulsants

**Injections:**
- see IPM Guideline

**Surgery:**
- if documented compression

**Not Recommended:**
- bed rest

#### GOALS OF TREATMENT

**Recommend RTW:**
- sedentary ....................... 0-3 days
- light-med ...................... 7-17 days
- heavy .......................... 14-35 days

Contingent on assessment of functional capacity

#### IF GOALS NOT MET

**EMG to document neurological status**

**Consider psychological factors**
- see Psychological Guideline

**Administer standard psych assessment tool**
(such as ODI)

**Consider time-limited behavioral cognitive therapy**

**Functional capacity evaluation / vocational rehab**

**Functional restoration program**

**Spinal cord stimulation:**
- neurological pain > 6 months
- adequate psychological evaluation prior to SCS trial
- see psychological guideline
### Root Decompression (Back)

**Diagnosis**
- radiculopathy due to compression
  - symptoms in the distribution of a nerve root caused by compression of a herniated disc or altered bony anatomy

**Indications**
- failure to improve with appropriate chiropractic or physical treatment for aerobic and strength with documented compliance
- time: 4-6 weeks minimum (unless progressive neurological deficit)
- medications: steroids, NSAIDs and transforaminal injection

**Radiographic Indications**
- lateral disc herniation
- lateral recess stenosis
- spinal stenosis

**Surgery**
- administer standard tool (ODI) before and after surgery to document outcome
- hemilaminectomy, discectomy, laminectomy, laminectomy for stenosis

**Post-Operative Recovery**
- Chiropractic or PT rehabilitation for strength and aerobic capacity
- return to work:
  - temporary total disability up to 4 weeks
  - return to light or modified duty 4-8 weeks
  - return to full duty after 8 weeks

**MMI**
- 6 months
- impairment based on objective standard (per CT WC Statute)

### Fusion (Back)

**Diagnosis**
- spondylolytic spondylolisthesis
- degenerative spondylolisthesis
- recurrent disc herniation
- removal of facet for decompression
- instability (>4mm or 10 degrees)
- pseudoarthrosis from previous fusion

**Indications**
- failure to improve with at least 3 months of conservative care, documented compliance
- no long acting opioids
- smoking is an absolute contraindication to fusion surgery
- BMI >30 significantly increases the risks, complications and/or poor outcomes and should be objectively assessed prior to consideration of fusion.
- warning: signs of symptom amplification, narcotics, long time out of work, failed psychological screening

**Radiographic Indications**
- X-Rays (including obliques for spondylolisthesis)
- flexion extension views for instability
- MRI to assess adjacent levels
- Discography for appropriate clinical indications
- CT or SPECT to assess pseudoarthrosis

**Surgery**
- administer standard tool, ODI before and after surgery to document outcome
- consider psychological screening prior to fusion surgery
- one or two levels only
- posterolateral fusion (PLF)
- PSF + Pedicle screws
- TLIF
- ALIF + PSF + Pedicle Screws

**Post-Operative Recovery**
- Chiropractic or PT rehabilitation for strength and aerobic capacity
- return to work
- temporary total disability up to 16 weeks.
- return to light or modified duty depending on demand level

**MMI**
- 12 months
- impairment based on objective standard (per CT WC Statute)
Medical necessity for all injections must be documented with a clear description of the diagnosis and rationale for the injection.

Injured workers should be re-evaluated @ 2 weeks following any intervention to assess change in pain level, change in function (and hence work status), and to determine next steps in the treatment course if medically indicated. IPM treatments (‘blocks’) are generally not a treatment performed in isolation; it is important to look at the underlying cause and include functional based exercise programs along with injections.

All spinal injections must be performed with radiologic guidance, typically fluoroscopy is utilized. CT guided pain management injections should only be performed for specific indications and medical necessity must be documented. Ultrasound is a form of radiologic guidance being used for many different pain injections but cannot be recommended for spinal injections at this time.

All spinal injections should be accompanied with a report of both the diagnostic and therapeutic response. An injection that does not provide relief still provides diagnostic information as to what is not the cause of the pain. A lack of response to a particular intervention still provides useful information and that should be duly noted in the records. This will prevent further unnecessary injections for pain generating structures that have been found to not be the cause of pain.

For injured workers who fail to respond to treatment, alternative diagnoses should be considered. If the worker fails to respond to treatment that appears to be appropriate for the condition, evaluation of other barriers to improvement such as psychological issues should be considered.

Facet blocks are indicated for the diagnosis and treatment of axial low back pain with or without pseudoradiculary symptoms for pain that is suspected of arising from the facet joints. A history and physical examination should document the clinician’s rationale for this suspected diagnosis. Definitive diagnosis requires documenting the patient’s response to a diagnostic injection. Therapeutic facet blocks will only be considered as proper management when they provide at least 70% relief of the axial back symptoms and at least 3 months of pain relief and will be limited to a maximum of 3 sets of therapeutic facet injections/year. Patients obtaining only short term relief (less than 3 months) should be considered for more long lasting solutions, such as RF ablation.

Sacroiliac joint injections are appropriate for suspected sacroiliac joint pain. This should be specifically confirmed by history and physical examination and the clinician must document medical necessity. A diagnostic sacroiliac block can be used to confirm this diagnosis. A negative response indicates this is not the cause of the pain. Therapeutic sacroiliac joint injections will only be considered as proper management when they provide at least 3 months of pain relief and will be limited to a maximum of 3 injections/year.

Facet and sacroiliac joint injections should include steroid (unless otherwise contraindicated) in hopes of providing long term therapeutic effect and to improve the diagnostic specificity of these injections. It should be recognized that patients who have short term relief with these injections may benefit from rhizotomy to achieve longer term pain relief. Some patients can be managed with intermittent therapeutic facet and/or sacroiliac joint injections in hopes of providing long term therapeutic effect and to improve the diagnostic specificity of these injections. Patients obtaining only short term relief (less than 3 months) should be considered for more long lasting solutions, such as RF ablation. Some patients can be managed with intermittent therapeutic facet injections.

Repeat therapeutic injections/procedures are only indicated for those individuals who document sustained improvement in both pain and function, including improved ADL’s and work capacities for at least three months.

In addition, if the patient has significant bilateral pain, bilateral injections should be performed with the diagnostic injection so the clinician can better and more fully assess the etiology of the pain. Residual pain from joints that are not treated will confuse the diagnostic information that is obtained from a diagnostic block.

Radiofrequency ablation (Facet and sacroiliac rhizotomy) may be considered for patients who achieve at least 70% reduction of target symptoms along with improved function and ROM with a diagnostic injection (Note- facet and sacroiliac joint blocks are not expected to result in improvement of radicular symptoms). Radiofrequency ablation requires that the patient has had a facet medial branch mapping procedure; intra-articular injections are not diagnostic for determining the need for RF. Rhizotomy cannot be performed more frequently than once every 6 months.

If there is a question about the etiology of recurrent pain, re-evaluation and repeat diagnostic workup should be considered prior to repeat injections.

Epidural steroid injections are indicated for back pain that is felt to be radicular or discogenic in origin and for which there is a specific possible spinal cause. There are situations where epidural steroid injections may help with axial low back pain, such as a central disc herniation, spinal stenosis, and/or other discogenic pain problems. A diagnosis of discogenic back pain is often a diagnosis of exclusion and other causes of back pain should be evaluated before considering ESIs for treatment of axial back pain. Epidural steroid injections may not be performed without an MRI documenting the specific location and extent of spinal pathology. The routine performance of three epidural steroid injections is not appropriate and results in unnecessary treatment. After each injection, the response should be documented both for pain and functional improvement; if a repeat injection is required medical necessity should be documented even if a series of injections has been approved.

Pain can arise out of multiple structures and therefore can be multifactorial in origin, nevertheless it is not expected that every single injured worker with back pain will require every single different type of injection, and in fact such practice is not recommended and is strongly discouraged.

Epidural Steroid Injections (ESI) are indicated for the treatment of a radiculopathy/ radiculitis with symptoms of pain in a radicular distribution, which can be associated with numbness, tingling, and/or weakness in that nerve root distribution. A lack of response should lead the clinician to reconsider the diagnosis or look for alternative treatment options. Medical necessity for all injections must be documented with a clear description of the symptoms, physical findings, diagnosis and rationale for the injection.

Injured workers should be re-evaluated @ 2 weeks following any intervention to assess change in pain level, change in function (and hence work status), and to determine next steps in the treatment course if medically indicated. IPM treatments (‘blocks’) are generally not a treatment performed in isolation; it is important to look at the underlying cause and include functional based exercise programs along with injections.

All spinal injections should be accompanied with a report of both the diagnostic and therapeutic response. An injection that does not provide relief still provides diagnostic information as to what is not the cause of the pain. This will prevent further unnecessary injections for structures that have been found not to be the cause of pain.

Earlier intervention with an ESI may help to speed recovery and promote progress in PT and therefore should be considered in the management of an acute radiculopathy that is not responding to conservative management.

Epidural steroid injections may not be performed without an MRI documenting the specific location and extent of spinal pathology and should be correlated with neurologic findings.

Delivery of medication to the location of nerve irritation is the key to success. Injections require radiologic guidance for accuracy and safety. All spinal injections must be performed with radiologic guidance, typically fluoroscopy. CT guided pain management injections should only be performed for specific indications and medical necessity must be documented. Ultrasound is not recommended for spinal injections at this time.

There are several different approaches to the epidural space but delivery of medication as close as possible to the target location is helpful to optimize outcomes. The choice between intrameningeal, transforaminal, and catherized approaches will be left to the clinician but the risks and benefits of the various approaches should be carefully considered when deciding technique.

The routine performance of three epidural steroid injections is not appropriate and results in unnecessary treatment. After each injection, the response should be documented both for pain and functional improvement; if a repeat injection is required medical necessity must be documented.

Injured Workers who do not respond with sustained benefit should be considered for definitive decompression of the involved nerve root(s).
### SHOULDER PAIN HISTORY AND PHYSICAL EXAMINATION

#### HISTORY OF PRESENT ILLNESS

**Description of injury:**
- details of events before, during, and immediately after the alleged injury, including the mechanism of injury

**Identification of body parts involved:**
- location of pain
- characteristics of the pain
- distribution of the pain symptoms
- frequency and duration of symptoms
- alleviating / exacerbating factors

Any significant side effects from previous medications should be noted.

The history should include the presence and distribution of any numbness, paresthesias, or weakness.

A visual analog pain scale should be used and monitored at each visit. The patient should be asked their current rating, average over the last week, and range from low to high.

Note any history of emotional and/or psychological response to the current injury.

#### MEDICATIONS

**History should include previous medications taken for this injury and a list of all current medications including dose and frequency.**

Any significant side effects from previous medications should be noted.

#### ALLERGIES

**Medication allergies should be verified at every visit.**

#### PAST MEDICAL / SURGICAL HISTORY

**Identify any previous occupational and non-occupational injuries to the same area.**

**Determine if the patient has any history of non-traumatic shoulder problems such as arthritis, diabetes mellitus, cancer, surgery etc.**

Document any prior shoulder treatment, chronic or recurrent symptoms, response to previous treatment, and any functional limitations or previous restrictions in work capacity.

#### SOCIAL HISTORY

**Identify:**
- smoking
- alcohol use
- other drug use
- vocational activities
- recreational activities
- secondary gain/
histrionics
- psychological profile

#### REVIEW OF SYSTEMS

**Identify systemic disease symptoms:**
- cardiac
- endocrine
- gastrointestinal
- hematological
- infectious
- neurologic
- neoplastic
- renal
- rheumatologic
- other

In cases where the mechanism of injury, history, or clinical presentation suggests a possible severe injury, additional evaluation is indicated.

#### PHYSICAL EXAMINATION

**Vital signs:**
- height
- weight
- general appearance, including posture
- any pain behaviors

**Signs of symptom amplification should be noted.**

**Visual inspection of shoulder:**
- range of motion
- stability anterior, inferior, posterior
- muscle atrophy and definition
- skin examination, i.e., temperature, scars, discoloration
- neurologic exam motor and sensory with reflexes
- strength testing (supraspinatus thumbs down test, external rotation, speed’s test, Yergason’s, Hawkins’, O’Brien test, etc.)
- vascular exam pulses and capillary refill (rule out thoracic outlet)
- AC joint or acromioclavicular joint pain
- subacromial vs. glenohumeral pathology
- rule out cardiac, i.e., myocardial infarction or failure
- rule out pulmonary etiology, i.e., carcinoma, or embolus, pleurisy
- cervical etiologies (thorough cervical exam)
- autoimmune diseases (rheumatoid, lupus, ankylosing spondylitis, etc.)
- Lyme Disease vs. infectious process
- neoplasm primary vs. metastatic (benign vs. malignant)
- post traumatic (previous fracture)
- congenital
- metabolic gout, pseudogout, diabetes mellitus
- birth trauma (nerve palsy)
- neurologic causes
- iatrogenic (post-surgical)
- malingering, adhesive capulitis / frozen shoulder
- psychologic or psychiatric phenomenon (depression, anxiety, hysteria, emotional disorders, behavioural disorders, and motivational)

In cases where the mechanism of injury, history, or clinical presentation suggests a possible severe injury, additional evaluation is indicated.
### Diagnostic Criteria

On initial visit:
- complete history
- physical examination
- pain diagram

Height and weight (BMI)

On each visit document:
- primary diagnosis
- precise location and character of pain
- VAS pain level
- exam pertinent to injured body part
- functional capacity
- appraisal of ADLs and functional activity

Work capacity and status

### Diagnostic Studies

Recommended:
- X-Rays, if indicated by amount of trauma or based on documented medical suspicion

No MRI

No CT Scan

### Treatment

Recommended:
- ice / heat
- rest / immobilization
- physical therapy / rehabilitation  
  - 4 to 6 weeks
- chiropractic care
  - maximum 12 weeks

Medications:
- nonsteroidal anti-inflammatory drugs
- analgesics
- antispasmodics
- psychotropics

Injections / Blocks:
- steroids with documentation of result and duration including medicines and dosage

Surgery may be indicated for some acute tears of rotator cuff, labrum, capsule, biceps or displaced fractures (see surgery guidelines on page 3).

Non-Consensus Modalities:
- PRP (platelet rich injections)
- acupuncture
- hyaluronic acid injections
- stem cell preparations

### Goals of Treatment

Recommend Return To Work:
- Non-Surgical:
  - generally light duty within 3 to 4 weeks
  - full duty within 6 to 8 weeks for most cases

Contingent on assessment of functional capacity

### If Goals Not Met

Document:
- compliance
- no shows / cancellations
- effort: clinic
- effort: home

Refer to orthopedic specialist after 2 weeks with primary care or occupational center with no positive result or benefit in symptoms with regard to clinical exam and history.
# Subacute Shoulder Injury (1-3 Months)

## Diagnostic Criteria
- On initial visit:
  - complete history
  - physical examination
  - pain diagram
  - Height and weight (BMI)
- On each visit document:
  - primary diagnosis
  - precise location and character of pain
  - VAS pain level
  - current meds
  - exam pertinent to injured body part
  - functional capacity
  - appraisal of ADLs and functional activity
  - Work capacity and status
  - Appraise compliance
  - Consider specialty referral, if not improving

## Diagnostic Studies
- Recommended, if clinically indicated:
  - X-Ray neck and shoulder
  - MRI with and without gadolinium
  - CT Scan
  - Ultrasound
  - bone scan
  - nuclear testing
  - white blood cell tagged, indium scans
  - neuro conductive, i.e., EMG testing

## Treatment
- **Chiropractic**
  - maximum 12 weeks
- **Physical Therapy**
  - maximum 6 weeks
- **Medications**:
  - nonsteroidal anti-inflammatory drugs (NSAIDs)
  - antispasmodics
  - analgesics
  - psychotropics
- **Injections / Blocks**:
  - steroids with documentation of result and duration
- **Open Surgery or Arthroscopic Surgery**
  - surgical correlates (positive)
    - young age
    - dominant extremity
    - acute event (i.e., less than 3 months duration)
    - acute symptomatology
  - surgical correlates (negative)
    - smoking
    - diabetic / immunosuppression
    - previous surgery
    - obesity / deconditioned
    - workers’ compensation causality
    - cervical disease
    - porcine xenograft
    - multiple physician or caregivers’ involvement
    - chronicity (i.e., more than 3 months of symptoms since injury)
    - retraction or atrophy of cuff or shoulder musculature
  - consensus opinion:
    - asymptomatic full or partial rotator cuff tears are NOT surgical candidates
- **Rehabilitation Protocol (post-surgical)**:
  - 2 to 3 times per week for 4 to 6 weeks (extendable)
  - re-evaluate every 4 to 6 weeks by clinical and treating physician
  - physical therapy for three month maximum, accumulative in nature with the exception of special circumstances

## Goals of Treatment
- **Recommend RTW**:
  - Non-Surgical:
    - generally light duty within 3 to 4 weeks
    - full duty within 6 to 8 weeks for most cases
  - Surgical:
    - light duty within 4 to 6 weeks for most surgical interventions
    - full duty within 8 to 12 weeks for most surgical interventions
    - potentially longer for rotator cuff repairs especially for manual laborers
    - contingent on assessment of functional capacity predicated on the treater’s judgment with second opinion when appropriate

## If Goals Not Met
- Consider alternative cause
- Consider psychological factors
  - see psychological guideline
- **Second Opinion**:
  - after 3 to 6 months of non-surgical or conservative treatment without benefit
  - after 6 to 12 months post-surgical with poor result
- At any time during treatment, the patient should be given the option for second opinion if there is an apparent physician-patient problem.

## Non-Consensus Modalities:
- PRP (platelet rich injections)
- hyaluronic acid injections
- acupuncture
- stem cell preparations
# Chronic Shoulder Injury (Greater than 3 Months)

## Diagnostic Criteria

On initial visit:
- complete history
- physical examination
- pain diagram

Height and weight (BMI)

On each visit document:
- primary diagnosis
- precise location and character of pain
- VAS pain level
- current meds
- exam pertinent to injured body part
- functional capacity
- appraisal of ADLs and functional activity

Work capacity and status

Appraise compliance

Consider specialty referral, if not improving

## Diagnostic Studies

Recommended, if clinically indicated:
- X-Ray neck and shoulder
- MRI with and without gadolinium
- CT Scan
- Ultrasound
- bone scan
- nuclear testing
- white blood cell tagged, indium scans
- neuro conductive, i.e., EMG testing

## Treatment

Chiropractic
- maximum 12 weeks

Physical Therapy
- maximum 6 weeks

Medications:
- nonsteroidal anti-inflammatory drugs
- analgesics
- antispasmodics
- psychotropics

Injections / Blocks:
- steroids with documentation of result and duration

Open Surgery or Arthroscopic Surgery
- surgical correlates (positive)
  - young age
  - dominant extremity
- surgical correlates (negative)
  - smoking
  - diabetic / immunosuppression
  - obesity / deconditioned
  - cervical disease
  - multiple physician or caregivers’ involvement
  - chronicity (i.e., more than 3 months of symptoms since injury)
  - retraction or atrophy of cuff or shoulder musculature
- consensus opinion:
  - asymptomatic full or partial rotator cuff tears are NOT surgical candidates

Rehabilitation Protocol (post-surgical):
- 2 to 3 times per week for 4 to 6 weeks (extendable)
- re-evaluate every 4 to 6 weeks by clinical and treating physician
- physical therapy for three month maximum, accumulative in nature with the exception of special circumstances

Non-Consensus Modalities:
- PRP (platelet rich injections)
- acupuncture
- hyaluronic acid injections
- stem cell preparations

## Goals of Treatment

Recommend RTW:
- Non-Surgical:
  - generally light duty within 3 to 4 weeks
  - full duty within 6 to 8 weeks for most cases
- Surgical:
  - light duty within 4 to 6 weeks for most surgical interventions
  - full duty within 8 to 12 weeks for most surgical interventions
  - potentially longer for rotator cuff repairs especially for manual laborers

Rehabilitation Protocol (post-surgical):
- contingent on assessment of functional capacity predicated on the treater’s judgment with second opinion when appropriate

## If Goals Not Met

Consider alternative cause

Consider psychological factors
- see psychological guideline

Second Opinion:
- after 3 to 6 months of non-surgical or conservative treatment without benefit
- after 6 to 12 months post-surgical with poor result

At any time during treatment, the patient should be given the option for second opinion if there is an apparent physician-patient problem.
# Hand/Wrist/Elbow Treatment Guidelines

## Contents

<table>
<thead>
<tr>
<th>Section</th>
</tr>
</thead>
<tbody>
<tr>
<td>I. Introduction</td>
</tr>
<tr>
<td>II. Soft Tissue Injuries: Tendinopathies/Tendonitis/Sprains of the Hand, Wrist, and Elbow</td>
</tr>
<tr>
<td>III. Nerve Compression Syndromes of the Hand, Wrist, and Elbow</td>
</tr>
<tr>
<td>IV. Fractures and Dislocations of the Hand, Wrist, and Elbow</td>
</tr>
<tr>
<td>V. Osteoarthritis of the Hand, Wrist, and Elbow</td>
</tr>
</tbody>
</table>

## Objectives

- Injuries to the upper extremity in the workplace are common. The following sections review common injuries to the hand, wrist, and elbow.

The guidelines are not intended to be all-inclusive, nor absolute with respect to recommendations. The Commission recognizes the variability inherent in injuries and the importance of individualized treatment for the injured worker.

The recommendations should not be construed as a rule, as the ultimate judgment regarding care of a patient must be made by the physician in light of all circumstances presented. These guidelines are intended as an outline for those participating in the care of injured workers to facilitate appropriate care in the most expeditious and effective manner.

These guidelines specifically do not address causation. Many conditions have clear causation such as a witnessed fall and fracture at work, yet many do not.

The Commission recognizes the importance of assessment by providers of each individual claim based upon all data provided and in accordance with published data to determine causation. As these factors are unique to each claim, it is beyond the scope of this document to comment on causation for diagnoses included in this document.

## General Guidelines

- These guidelines are divided into sections based upon diagnosis. Practitioners are responsible for diagnosis.

- An overview is provided in each section for general considerations with respect to management and expectations for particular pathology. Tables specific to diagnoses follow with more specific recommendations for evaluation, clinical studies and timeframe for specialty referral, surgical intervention, and recovery.

- Many of the tables refer to therapy as a treatment option. Specific recommendations are noted for CHT (Certified Hand Therapy) or OT (occupational therapy). We recognize that many Physical Therapists (PT), as well as Chiropractors, also work with the hand and elbow. When possible, hand therapy is recommended to maximize therapy benefit.

## Work Status

- Within the guidelines, there is an attempt to clarify timing of return to work for given diagnoses. Accordingly, ranges are given for time out of work (Totally Disabled), Return to Work (With Restrictions), and Return to Work (Without Restrictions).

- Restrictions are specific to patient, injury, and work environment. Clinical issues may offset timelines.

- The ranges include no Temporary Total Disability, which is typical in non-operative sprains, strains, and tendinopathy, to weeks in post-operative and more severe traumatic scenarios.

- In some cases, these times may be significantly shortened. In others, patients may have chronic injuries resulting in pain or functional deficits that require further assessment such as Functional Capacity Evaluation (FCE), or potentially candid discussion regarding symptom chronicity and limitations with regard to further management.

## Soft Tissue Injuries: Tendinopathies/Tendonitis/Sprains of the Hand, Wrist, and Elbow

- Overview – Evaluation – Treatment
- Sprain/Strain of the Hand, Wrist, and Forearm
- Wrist Tendinopathy (e.g., DeQuervain’s, Dorsal, and Volar Wrist Tenosynovitis)
- Stenosing Tenosynovitis (Trigger Finger/Thumb)
- Lateral and Medial Epicondylitis (Tennis and Golfer’s Elbow)
- Contusion, Laceration, and Crush to the Hand/Wrist/Elbow
- Bicep and Tricep Injuries of the Elbow
- Wrist Pain (Acute)
- Wrist Pain (2 weeks after injury)
- Wrist Pain (6-12 weeks after injury)
- Wrist Pain (Chronic: greater than 3 months)

## Nerve Compression Syndromes of the Hand, Wrist, and Elbow

- Overview – Identifying Nerve Injuries – Prognosis
- Carpal Tunnel Syndrome
- Cubital Tunnel Syndrome
- Other Compression Neuropathies (Pronator Syndrome, Anterior Interosseus Syndrome, Radial Nerve Palsy, Radial Tunnel Syndrome, Superficial Radial Nerve Palsy, Ulnar Tunnel Syndrome)

## Fractures and Dislocations of the Hand, Wrist, and Elbow

- Overview – Initial Diagnosis and Management – Emergencies – Referral – Surgical Indications – Return to Work
- Fractures of Metacarpals and Phalanges
- Fractures of Wrist
- Fractures of Elbow

## Osteoarthritis of the Hand, Wrist, and Elbow

- Overview – Evaluation – Treatment
- Osteoarthritis
<table>
<thead>
<tr>
<th><strong>OVERVIEW</strong></th>
<th><strong>EVALUATION</strong></th>
<th><strong>TREATMENT</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Tendon injuries are some of the most common injuries sustained in the workplace. These injuries include acute sprains and strains, in addition to more chronic inflammatory/degenerative conditions of tendon. Ligament sprains, degeneration, and tearing are similar with both acute and chronic injury patterns. Treatment of common &quot;tendonitis&quot; has long been directed at the presumptive inflammation. This terminology implies that pain arises from inflammation, while data has shown little of this is actually present. Current studies are underway to further understand the pathophysiology of tendon-associated pain. Occasionally, acute strain (tendon) or sprain (ligament) may be well documented based on specific injury. These injuries will typically follow a common pathway of initial inflammation, followed by healing phase, and can often be treated by supportive means. More chronic injury will often present with peritendinous fibrosis or retinacular thickening, as seen in stenosing tenosynovitis or de Quervain's tenosynovitis.</td>
<td>Workers need to be evaluated within the context of their occupation. These injuries may occur with a specific acute injury or in the process of more chronic overuse of the tendon, with the pathophysiology as noted above. Tendon function would be expected to correlate with the described injury pattern. The evaluator should be able to identify the specific structure contributing to the pain complaint, and direct management specific to that tendon or ligament.</td>
<td>Treatment for tendon injuries is directed at the type of injury, and in many cases the tendon or ligament involved. While common management – including rest and anti-inflammatory medications – remain standard practice, it should be noted that there is limited information as to the efficacy of these treatments. Many acute injuries will subside well with this standard approach; some more chronic tendinopathies may not. Furthermore, different tendons clearly respond differently to different treatments (e.g. corticosteroid injections have a documented “cure” rate for stenosing tenosynovitis and yet, more recently, have been shown to only have temporary palliative effects in lateral epicondylitis).</td>
</tr>
</tbody>
</table>
**INITIAL EVALUATION**

- Complete History
- Physical Exam

**Specifics:**
- location of pain
- mechanism of injury
- work / hobby / sports Hx
- ROM
- instability
- Crepitus
- VAS / functional ability

**Follow-Up:**
- interval history
- pertinent exam
- VAS / functional ability

**DIAGNOSTIC STUDIES**

As indicated:
- X-Ray
- MRI
- Ultrasound

**TREATMENT**

- Splint / Brace
- NSAIDs

**Therapy:**
- CHT
- OT

Consider steroid injection(s).

**Follow-Up:**
- 1-2 weeks, if work modified
- 4 weeks, if work not modified

**RECOVERY**

Most soft tissue injuries are stable within 10-14 days.

Frequently indicated after casting or surgery, as hand is susceptible to significant loss of motion:
- CHT
- OT

**WORK CAPACITY**

- Totally Disabled..................... 0-2 weeks
- With Restrictions ................2-4 weeks
- Without Restrictions ..........4-12 weeks
- MMI.................................6-12 months

**MEDICAL PROTOCOLS**

**HAND**

- PAGE 3 of 22
## WRIST TENDINOPATHY (e.g., de QUERVAIN’S, DORSAL AND VOLAR WRIST TENOSYNOVITIS)

### Initial Evaluation
- Complete History
- Physical Exam

### Diagnostic Studies
- As indicated:
  - X-Ray
  - MRI

### Treatment
- Initial:
  - splinting
  - medications
  - steroid injection(s)
  - therapy
    - CHT
    - OT
  - activity modification

  If no improvement after 2 weeks, recommend referral to a specialist.

  Continued non-surgical treatment or surgical treatment may be appropriate.

### Recovery
- After surgery:
  - 1-2 weeks
    - sutures out
    - splinting, as needed, for comfort
  - 2-4 weeks
    - progress to gentle active ROM
    - consider therapy
  - 4-6 weeks
    - continue with active ROM exercises
    - begin gentle resistive exercises
  - 6+ weeks
    - progress to normal activity

### Work Capacity
- Totally Disabled: 0-2 weeks
- With Restrictions: 2-6 weeks
- Without Restrictions: 6-12 weeks
- MMI: 6-12 months

### Medical Protocols: Hand – Page 4 of 22
STENOSING TENOSYNOVITIS (TRIGGER FINGER/THUMB)

INITIAL EVALUATION

Complete History

Physical Exam

Specifics:
- acute / chronic
- which digit(s)
- locking
- location of pain
- mechanism of Injury
- work / hobby / sports Hx
- ROM
- Diabetes Hx
- VAS / functional ability

DIAGNOSTIC STUDIES

X-Ray may be indicated

Other studies occasionally necessary:
- MRI
- Ultrasound

TREATMENT

NSAIDs

Steroid Injection(s)

Therapy:
- CHT
- OT

Activity Modification

If no improvement within 2 weeks recommend referral to specialist

RECOVERY

After surgery:
- 1-2 weeks
  - sutures out
  - splinting, as needed, for comfort
- 2-4 weeks
  - progress to gentle active ROM
  - consider therapy
- 4-6 weeks
  - continue with active ROM exercises
  - begin gentle resistive exercises
- 6+ weeks
  - progress to normal activity

WORK CAPACITY

Totally Disabled.................. 0-2 weeks

With Restrictions ................. 2-6 weeks

Without Restrictions .............. 6-12 weeks

MMI........................................ 6-12 months
### Initial Evaluation

- Complete History
- Physical Exam

**Specifics:**
- location of pain (epicondyle vs. forearm musculature)
- mechanism of injury
- work / hobby / sports Hx
- ROM
- wrist extension test
- radial neuritis
- acute / chronic
- VAS / functional ability

### Diagnostic Studies

- X-Ray
- Other studies occasionally necessary:
  - MRI
  - Ultrasound

### Treatment

- Activity Modification
- Brace / Splint
- NSAIDs
- Therapy:
  - CHT
  - OT
- Steroid Injection(s)
- Surgery:
  - most commonly improves without surgical intervention
  - surgery frequently delayed until 6-12 months after onset of symptoms, with the expectation that patient may improve with non-op management

### Recovery

- After surgery:
  - 1-2 weeks
    - sutures out
    - splinting, as needed, for comfort
  - 2-4 weeks
    - progress to gentle active ROM
    - consider therapy
  - 4-6 weeks
    - continue with active ROM exercises
    - begin gentle resistive exercises
  - 6+ weeks
    - progress to normal activity

With non-operative management, prolonged recovery of 4-6 months is not unusual.

Appropriate work modifications may be necessary.

### Work Capacity

- Totally Disabled ..................... 0-4 weeks
- With Restrictions ................... 2-12 weeks
- Without Restrictions .............. 6-24 weeks
- MMI ........................................ 12 months
## Initial Evaluation

- Complete History
- Physical Exam

### Specifics:
- mechanism of injury
- location of pain
- interval Tx
- Abx / Tetanus
- document each tendon / nerve function
- VAS / functional ability

### Follow-Up:
- interval history
- pertinent exam
- VAS / functional ability

## Diagnostic Studies

- **X-Ray:**
  - at least 2 orthogonal X-Rays (typically 3)
- Considered for:
  - crush
  - significant contusion
  - laceration (if foreign material may be present)
- Other studies, depending upon indications:
  - Ultrasound
  - MRI

## Treatment

### Initial Management:
- open wounds irrigated and closed, when clean
- consider Abx
- splint for comfort or tendon deficit

### Emergent Referral:
- compartment concern
- vascular compromise
- evolving neurologic status

### Early Referral:
- tendon deficit
- neurologic deficit (static)
- concern for ligament instability (beyond sprain)

### Definitive management based upon injured structures.

### Surgery indicated for:
- tendon laceration
- nerve laceration
- ligament rupture

## Recovery

- Most soft tissue injuries are stable within 10-14 days.
- Tendon repairs require specific post-operative splinting protocols under guidance of therapist.
- Frequently indicated after casting or surgery, as hand is susceptible to significant loss of motion:
  - CHT
  - OT
- Specific early therapy program, with splinting mandatory, for tendon repairs:
  - Certified Hand Therapist critical

## Work Capacity

- No surgery required:
  - Totally Disabled ..................... 0-2 weeks
  - With Restrictions ................... 2-6 weeks
  - Without Restrictions .............. 6-12 weeks

- Post-surgery:
  - Totally Disabled ..................... 0-2 weeks
  - With Restrictions ................... 2-6 weeks
  - Without Restrictions .............. 6-12 weeks

- MMI ........................................ 6-12 months
**INITIAL EVALUATION**

- Complete History
- Physical Exam
- Specifics:
  - location of pain
  - deformity
  - mechanism of injury
    (usually single episode traumatic for complete ruptures and can be repetitive for partial ruptures/"tendinosis")
  - Detailed history of potential associated aggravating activities (i.e., weight lifting, use of fluoroquinolone antibiotics)
- VAS / functional Ability

**DIAGNOSTIC STUDIES**

- Radiographs:
  - rule out other causes or bone avulsion injuries
- MRI:
  - study of choice, especially for evaluating partial (or incomplete) ruptures

With some complete ruptures, exam findings are obvious enough to complete the diagnosis without diagnostic tests.

Confirm complete or partial.

**TREATMENT**

**Partial ruptures:**
- bicep tears
  - lifting, pulling, climbing restrictions
- partial triceps
  - pushing, weight-bearing, climbing restrictions

Non-operative modalities:
- rest
  - work and personal restrictions
- physical therapy
  - more effective for triceps
- injections
  - not recommended
- reassessment every 2-6 wks

**Complete ruptures:**
- triceps
  - critical to repair
- biceps
  - optional to repair depending on patients needs / desires

Surgical repair optimal within 3 weeks of acute complete rupture to minimize detrimental effects of muscle retraction / scarring and need of grafts

**RECOVERY**

Pain relief and functional strength recovery

Partial rupture:
- consider surgical repair after failure of non-operative methods

**WORK CAPACITY**

RTW on TPD ................. 0-4 days, if no surgery planned

Totally Disabled ............... 0-2 weeks

With Restrictions ............. 2-12 weeks

Without Restrictions .......... 6-24 weeks

MMI ........................................ 1 year post-operatively
# Wrist Pain (Acute)

## Initial Evaluation
- Complete History
- Physical Exam

## Specifics:
- Location of pain
- Mechanism of injury
- Work / hobby / sports Hx
- ROM
- DRUJ pain / instability
- Crepitus
- Scaphoid Shift
- VAS / functional ability

## Diagnostic Studies
- Plain film X-Rays:
  - minimum 3 views

Consider 7-view formal wrist series films and/or contralateral wrist for comparison.

## Treatment
- Normal X-Ray:
  - splint continuously for 2 weeks
  - NSAIDs
  - ice and heat
  - rest
  - reassess

Abnormal X-Ray:
- treat for appropriate fracture or acute ligament injury (see other Protocols)

## Recovery
- 2 weeks

## Work Capacity
- Totally Disabled .................. 0-2 weeks
- With Restrictions ............... 2-6 weeks
- Without Restrictions .......... 6-12 weeks
- MMI .................................. 6-12 months
### Initial Evaluation

2 weeks after injury

### Diagnostic Studies

Repeat plain film X-Rays with special views, if needed (e.g. Scaphoid views).

### Treatment

**Still normal X-Rays:**
- consider cortisone injection
- continue NSAIDs
- consider occupational therapy, if low suspicion
- splint continuously 4 more weeks for significant symptoms and a high suspicion

**Abnormal X-Rays:**
- treat for appropriate fracture or ligament injury (see other Protocols)

For DISI / VISI, scapholunate gap, clunking or signs of instability, positive scaphoid shift test, consider:
- MRI
- arthrogram / arthroscopy
- surgery

### Recovery

4 weeks

### Work Capacity

| MMI | 6-12 months |
| Work Capacity | |
| Totally Disabled | 0-2 weeks |
| With Restrictions | 2-6 weeks |
| Without Restrictions | 6-12 weeks |
**WRIST PAIN (6-12 WEEKS AFTER INJURY)**

<table>
<thead>
<tr>
<th>INITIAL EVALUATION</th>
<th>DIAGNOSTIC STUDIES</th>
<th>TREATMENT</th>
<th>RECOVERY</th>
<th>WORK CAPACITY</th>
</tr>
</thead>
</table>
| 6-12 weeks after injury | Physical Exam:  
- is wrist pain localizing? | Reassess  
If non-tender or improving:  
- wean splint  
- start occupational therapy  
- consider injection, if not yet done  
If still tender:  
- MRI arthrogram  
If MRI / A abnormal:  
- arthroscopy / surgery  
If MRI / A normal:  
- Occupational therapy  
- consider cortisone injection  
- consider diagnostic arthroscopy | 4 weeks |  
Totally Disabled .................. 0-2 weeks  
With Restrictions ................. 2-6 weeks  
Without Restrictions .............. 6-12 weeks  
MMI ........................................ 6-12 months |
### WRIST PAIN (CHRONIC: GREATER THAN 3 MONTHS)

<table>
<thead>
<tr>
<th>INITIAL EVALUATION</th>
<th>DIAGNOSTIC STUDIES</th>
<th>TREATMENT</th>
<th>RECOVERY</th>
<th>WORK CAPACITY</th>
</tr>
</thead>
</table>
| chronic wrist pain – greater than 3 months | Wrist exam:  
- localizing pain or signs of instability  
Reassess in 4 weeks | Repeat X-Rays, if not already done.  
If normal:  
- consider splint  
- NSAIDs  
- OT  
- cortisone injection  
If still significantly tender:  
- MRI +/- Arthrogram  
If abnormal:  
- arthroscopy / surgery  
If normal, consider:  
- diagnostic arthroscopy  
- bone scan  
- rheumatologic lab studies  
- steroid injection(s)  
If negative MRI / A, negative arthroscopy, negative X-Rays, ongoing pain despite steroid injections, splinting, therapy – then consider:  
- rheumatology referral  
- acupuncture  
- ergonomic changes  
- job modifications or job change  
- vocational training  
- candid discussion that not all pain has a surgical remedy and a hand surgeon no longer needed  
- may always have some wrist discomfort  
Discharge | 4 weeks | One or two-handed duty with restrictions, if necessary.  
Return to some type of work, possible with splint. |
### OVERVIEW

Work-related nerve injuries can occur through repetitive trauma, blunt injury or via penetrating and open injuries.

Onset can be acute, subacute, or chronic. Symptoms vary on presentation and depend on the degree and type of nerve injury.

Nerve injuries can be classified as Neuropraxia, Axonotmesis and Neurotmesis:
- Neuropraxia represents physiological dysfunction of the nerve without anatomic disruption.
- Axonotmesis represents anatomic disruption with interruption and injury to the nerve axon.
- Neurotmesis is defined as disruption of all elements of the nerve.

In the case of Axonotmesis and Neurotmesis, Wallerian degeneration of the distal nerve end takes place. This process occurs before nerve regeneration and basically is a debridement process of the distal stump of the nerve to aid in nerve regeneration.

Nerve healing takes place in an organized, sequential manner; first with Wallerian degeneration of the distal nerve ending, followed by axonal regeneration and growth, and finally nerve reinnervation.

Unfortunately, the process of nerve healing is variable and, thus, the time required to recover from nerve injury is often difficult to predict.

### IDENTIFYING NERVE INJURIES

Understanding the functional anatomy of nerve is critical in making the correct diagnosis of nerve injury.

Identification of sensory and / or muscle loss will help identify the location of nerve injury and possibly help with prognosis predictions. Supplemental testing such as nerve conduction testing and electromyography are also often helpful in identifying not only the location of nerve injury, but may also indicate the severity of injury.

These tests can also help provide information concerning degree of healing of the nerve. Although these tests are helpful, they should not be the only determining factor in recommending treatment.

Based upon current literature, strong consideration should be given to pre-operative electrodiagnostic testing to assess for concomitant or coexisting neuropathy, and to serve as a baseline study for comparative purposes should another study be needed following treatment.

It is important to recall that these studies have a well-documented false-negative rate, and the presence of a negative study does not necessarily indicate absence of disease or necessity of treatment.

### PROGNOSIS

Prognosis for peripheral nerve injuries is often difficult to determine, but with a thorough neurological exam based on the clear understanding of the anatomy and the use of supplemental testing – such as nerve conduction tests and electromyography – treatment plans can be developed and predictions for return to work status made.
CARPAL TUNNEL SYNDROME

</tbody>
</table>

Note that electrodiagnostic studies are well recognized to be negative in Radial Tunnel Syndrome and proximal median nerve compression, but a positive result is significant, and the study serves as a baseline for comparison following treatment or surgery, and is therefore still recommended.

If no improvement after 2 weeks, consider referral to a specialist for continued non-surgical treatment or surgical treatment.

**FRACTURES AND DISLOCATIONS OF THE HAND, WRIST, AND ELBOW**

<table>
<thead>
<tr>
<th>OVERVIEW</th>
<th>INITIAL DIAGNOSIS AND MANAGEMENT</th>
<th>EMERGENCIES</th>
<th>REFERRAL INDICATIONS</th>
<th>RETURN TO WORK</th>
</tr>
</thead>
</table>
| Guidelines provided are intended to establish a consistent framework for initial evaluation and subsequent management for common workplace fractures of the upper extremity. These are guidelines provided to improve consistency, and providers should understand that these do not supersede individual circumstances, which should be appropriately documented. | Evaluation:  
- history and physical examination should include mechanism of injury and any other complaints from present injury  
- History should include:  
  - previous history of injury / fracture to the same body part  
  - sensory complaints  
  - history of smoking  
- Physical examination should include:  
  - documentation of any pain throughout limb  
  - status of skin (open or closed fracture, tenting, blistering)  
  - neurological examination (pre- and post-immobilization)  
  - tendon function  
  - degree of wound contamination  
  - any visible structures (e.g., lacerated tendon) should be noted  
- Radiographs:  
  - at least 2 orthogonal views of area of concern  
  - joints above and below fracture should be evaluated  
  - CT scan possible to further clarify fracture specifics, such as degree of joint displacement  
  - MRI possible for soft tissue injuries or to determine presence of scaphoid fracture  
- Management:  
  - Closed fractures  
    - Fractures and acute soft tissue injuries should be managed expeditiously. Fractures should be aligned and splinted, whenever possible, to avoid further soft tissue injuries and minimize pain. This is typically accomplished with longitudinal traction. Further reduction maneuvers should be limited to those with appropriate expertise.  
  - Open fractures  
    - Open fractures pose significant risk for infection. Time to administration of IV antibiotics and debridement in open fractures has been shown to be critically important to minimize infection risk. These should be transferred to appropriate center emergently. Wound irrigation and hemostasis, when possible, is appropriate. As with closed fractures, splinting is critical to reduce risk to other soft tissues and control pain. Further management may require hospitalization. Many hand injuries with minimal wound contamination may be managed with irrigation in office or ER setting and oral antibiotics.  
  - Open fractures should be made emergently in cases of contaminated wound, open fractures, concern for Compartment Syndrome, or evolving neurological deficit.  
  - Compartment Syndrome occurs when tissue pressure exceeds perfusion pressure and tissue ischemia results. In the upper extremity, the most common area of concern is the forearm. Compartment Syndrome in the hand can occur much less often and, while reported, occurrence isolated to the fingers is extremely rare. These are often associated with fracture and crush injuries.  
  - As tissue pressures increase, pain escalates. The compartments become tight, but may be covered by splint. The splints should be loosened to further investigate. Neurologic deficits and vascular occlusion occur later, usually after irreparable tissue necrosis. Early diagnosis is essential.  
  - Hallmark findings in Compartment Syndrome are pain out of proportion to exam, and pain with passive stretch. For example, in the forearm the scenario is much more common with fracture of the shaft of radius and ulna rather than at the wrist. Passive flexion and extension of the digits should normally be somewhat tolerable. Concern should be raised when there is little to no active motion, and small amounts of passive motion elicit severe pain.  
  - Neurologic injury:  
    - Neurologic deficits should be noted on initial examination. These are typically static and, as such, do not require emergent treatment, but should be evaluated immediately. However, change in neurological status following reduction or progression of neurologic deficit should be evaluated and managed emergently.  
  - Vascular injury:  
    - Loss of pulse or capillary refill is indicative of insult to the arterial inflow. Typical vascular deficit in the hand and wrist are a result of laceration to the artery or displaced fracture.  
  - Initial reduction is performed and vascular status is reevaluated. Persistent deficit or arterial laceration compromising distal perfusion should be referred to ED and managed emergently. | Referral to ED should be made emergently in cases of contaminated wound, open fractures, concern for Compartment Syndrome, or evolving neurological deficit.  
- Based upon position after reduction, or progression of displacement, surgery may be indicated to correct and maintain position.  
- Fractures often require operative intervention.  
- Fractures are reduced and immobilized initially.  
- Most fractures of the hand and wrist will be stable in 6-8 weeks, but often not fully healed.  
- Typically, these are transitioned to splints, to allow for range of motion and eventually strengthening while the fracture goes on to full healing.  
- Often, patients may be able to return to limited capacity within 2-4 weeks, depending on fracture, pain level, and degree of immobilization. |

### FRACTURES OF WRIST

#### INITIAL EVALUATION
- Complete History
- Physical Exam
  - location of pain
  - mechanism of injury
  - deformity
  - open wounds
  - compartments
  - instability
  - Crepitus

Must document neurological and vascular status pre- and post-reduction or splinting.

#### Interval Hx
- VAS / functional ability

#### DIAGNOSTIC STUDIES
- X-Ray:
  - at least 2 orthogonal views (typically 3)

- CT scan:
  - considered, if more information needed on fracture specifics

- MRI:
  - useful for occult fractures
  - should be considered – typically at 2 weeks – for exam concerning for scaphoid fracture with negative radiographs

- Specific X-Ray views:
  - concern for scaphoid injury with snuffbox tenderness – obtain “scaphoid view”
  - distal radius angulation best seen with “facet lateral” view (20 degrees off true lateral)

Things to look out for:
- scaphoid fractures often subtle; if snuffbox tenderness, obtain scaphoid view
  - when in doubt, splint

Perilunate injuries often missed

#### TREATMENT
- Wounds:
  - irrigate open wounds
  - begin Abx and refer immediately
  - reduction performed, if displaced
  - always splint

Emergent Referral:
- open fractures
- compartment concern
- vascular compromise
- evolving neurologic status

Early Referral:
- closed fractures with stable neurological status

Management:
- definitive management based upon fracture alignment and stability
  - may require cast vs. surgical reduction / fixation
  - surgical indication based upon patient age, fracture stability, and position
  - frequent – but not definitive – indications for surgery in distal radius
    - articular displacement
    - dorsal tilt > 10 deg
    - shortening > 3 mm

#### RECOVERY
- Most distal radius fractures require casting 4-6 weeks.

Surgical repair occasionally allows for earlier motion but not loading until healed.

Frequently indicated after casting or surgery, as hand is susceptible to significant loss of motion:
- CHT
- OT
  - typically 2 visits per week for 2-8 weeks

- complex regional pain syndrome (RSD) may necessitate substantially greater amount of therapy

#### WORK CAPACITY
- Totally Disabled............... 0-2 weeks
- With Restrictions ............. 2-6 weeks
- Without Restrictions .......... 6-12 weeks
- MMI............................... 6-12 months

Carpal fractures – and notably scaphoid – are slow to heal and may more than double above timeline.

---

**MEDICAL PROTOCOLS: HAND – PAGE 19 of 22**
# FRACTURES OF ELBOW

## INITIAL EVALUATION
- Complete History
- Physical Exam
- Specifics:
  - location of pain
  - mechanism of Injury
  - ROM
  - instability
  - Crepitus
- Detailed history of work injury, usually single traumatic event
- Detailed history of any previous elbow injuries/fractures
- Appropriate relevant neurovascular exam
- VAS / functional ability

## DIAGNOSTIC STUDIES
- Radiographs:
  - critical to obtain initially, and additional special views if necessary
- CT Scan:
  - often necessary to confirm treatment plan
- MRI:
  - occasionally useful to evaluate occult fractures

## TREATMENT
### Open fractures:
- treated acutely with direct emergency room evaluation and urgent surgical intervention
### Closed fractures:
- initial immobilization with or without a closed reduction, then acute referral to orthopedic surgeon
- surgically:
  - open reduction / internal fixation (ORIF):
    - scheduled typically less than two weeks
    - optimally less than one week for closed fractures (immediate for open fractures)

## RECOVERY
- Pain relief and functional strength recovery
- If goals not met:
  - most simple elbow fractures (i.e., single fractures not associated with dislocations) heal in 2-4 months
  - if a simple fracture treated non-operatively is not healed in 2-4 months, further specialist consultation and/or diagnostic tests (i.e., CT Scan) are necessary
  - complex fracture dislocations needing ORIF take much longer to heal and obtain functional recovery, not uncommonly 6-9 months

## WORK CAPACITY
- For non-operative/cast immobilization:
  - Totally Disabled............... 1-4 weeks
  - With Restrictions ............. 2-12 weeks
  - Without Restrictions .......... 6-12 weeks
- For open reduction/internal fixation:
  - Totally Disabled............... 1-4 weeks
  - With Restrictions ............. 2-12 weeks
  - Without Restrictions .......... 6-12 weeks
- MMI................................ 1 year
- Post-operative:
  - extended accordingly for complex cases, including at least 6 months after full RTW
OVERVIEW

Osteoarthritis (osteoarthrosis, DJD) is the most common disease of the joints. It is characterized by progressive deterioration and loss of articular cartilage, and by reactive changes at the margins of the joints and in the subchondral bone. Associated synovitis is common.

Clinical manifestations are characterized by progressive joint pain, stiffness, and enlargement.

Prevalence increases with age and is almost universal in persons over the age of 65. It is more common in women. Genetic, hormonal, and biomechanical factors also play a role.

Direct injury to joints can lead to post-traumatic arthritis, which may present in a delayed fashion. Most likely no specific type of manual labor can directly “cause” arthritis.

The role of repetitive trauma is controversial, but in certain scenarios it may worsen underlying and pre-existing arthritis.

EVALUATION

Osteoarthritis will present with focal / joint specific findings. These are not always painful, but may restrict range of motion.

Evaluation should focus on focal pain and mobility.

Radiographs are essential to diagnosis.

TREATMENT

There is no cure for cartilage wear.

Treatment is often directed to alleviate the associated painful synovitis, either by decreasing load on the affected joint through activity modification, bracing, medication, or injection.

Surgical treatment may offer relief after all conservative measures have been exhausted.
### Initial Evaluation

- **Complete History**
- **Physical Exam**

**Specifics:**
- Location of pain
- Mechanism of injury
- Work / hobby / sports Hx
- ROM
- Swelling
- Instability
- Crepitus
- Grip strength
- Grind Test (thumb CMC)
- Heberden’s / Bouchard’s

- Interval Hx
- VAS / functional ability

### Diagnostic Studies

- X-Rays

Controversial if repetitive strain without discreet injury materially and substantially aggravates underlying arthritis, or is pain part of the natural history of arthritis, and unrelated to job.

A remote injury can result in certain patterns of arthritis years later, such as SLAC wrist after scapholunate ligament injury. A patient presenting with an arthritis pattern that appears to be from an old injury may be experiencing the natural history of their original injury rather than an injury caused by work.

Consider blood work to rule out rheumatoid arthritis or other non-work related cause of arthritis.

### Treatment

- **Rest**
- **Splinting**
- **Steroidal / NSAIDs**
- **Heat**

**Topicals:**
- e.g., Diclofenac, Flector Patch, capsaiscin

**Steroid injection(s)**

**Therapy:**
- CHT
- OT

Arthritis may require long-term management as opposed to cure. Patients may never be completely pain free. Symptoms may wax and wane depending upon activity level.

Surgery is indicated for refractory cases, unresponsive to conservative measures, or interfering with activities of daily living and causing loss of work.

**Surgery:**
- Arthroplasty
- Arthrodesis

### Recovery

- Maximum 8 weeks of conservative treatment, including:
  - CHT
  - OT

- Recovery following surgery 3 months.

### Work Capacity

- Totally Disabled ..................... 0-2 weeks
- With Restrictions ................... 2-12 weeks
- Without Restrictions .............. 6-24 weeks
- MMI ...................................... 6-12 months

Return to work with permanent restrictions, if cannot perform full duty; otherwise consider alternative employment.

May need permanent restrictions following surgery

</tr>
</tbody>
</table>

**MEDICATIONS**

Examine Joints above / below:
- hip
- ankle

**Gait Pattern:**
- limp
- short arc
- avoidance

Evaluate non-knee-related issues:
- hip
- sciatica
- vascular

Consider autoimmune phenomenon and inflammatory etiologies, i.e.:
- gout
- lyme
- rheumatoid
- sepsis

Arthrofibrosis:
- separate guarding from true contracture
### Acute Traumatic or Overuse/Repetitive Stress (Less Than 4 Weeks)

#### Diagnostic Studies

Recommended:
- X-Rays, if indicated by trauma or medical suspicion
- MRI or CT, only if suggestion of locked knee, ligament instability, or suspicion of significant occult process

#### Treatment

Recommended:
- Ice / Heat:
  - elevation +/- compression
- Rest / Immobilization:
  - question crutches
- Physical Therapy:
  - 4-6 weeks (12-18 visits)
  - as indicated by progress
- Chiropractic Care:
  - 4-6 weeks (12-18 visits)
- Acupuncture
  - 4-6 weeks (12-18 visits)

Medications:
- NSAIDs
- analgesics
- antispasmodics
- psychotropics
- aspiration / injection, if necessary

#### Goals of Treatment

Recommend RTW – Non-Surgical:
- light duty .................. within 3-4 weeks (generally)
- full duty .................... within 6-8 weeks (for most cases)

Contingent on assessment of functional capacity

#### If Goals Not Met

Document:
- compliance
- no shows / cancellations
- effort: clinic
- effort: home

Refer to specialist:
- after 2 weeks with no positive result or benefit of symptoms with regard to clinical exam and history

---

**Medical Protocols: Knee**

Page 2 of 4
**SUBACUTE KNEE INJURY (1-3 MONTHS)**

### DIAGNOSTIC CRITERIA

- On initial visit:
  - complete history
  - physical examination
  - pain diagram

- Height and weight (BMI)

- On each visit document:
  - primary diagnosis
  - precise location and character of pain
  -VAS pain level
  - current medications
  - exam pertinent to injured body part
  - functional capacity
  - appraisal of ADLs and functional activity

- Work capacity and status
- Appraise compliance
- Consider specialty referral, if not improved

### DIAGNOSTIC STUDIES

Recommended, if clinically indicated:
- X-Ray of knee: question hip
- MRI: with or without contrast (if previous surgery)
- CT Scan: for some fractures, for tumor
- Ultrasound to rule out DVT
- Bone Scan to rule out:
  - contusion
  - infection
  - cancer
  - fatigue FX
- Nuclear Testing:
  - prosthetic loosening vs. infection
- White Blood Cell Tagged:
  - indium scan to rule out infection
- Neuro Conductive:
  - to rule out nerve compression injuries

### TREATMENT

**Recommended:**
- Chiropractic Care:
  - 6 to 8 weeks (18 to 24 visits)
- Physical Therapy:
  - 6 to 8 weeks (18 to 24 visits)

**Medications:**
- NSAIDs
- analgesics (oral or topical)
- antispasmodics
- psychotropics
- injection / aspiration
- steroid / hyaluronic acid

**Document result and duration.**

**Surgery:**
- dependent on DX and response to conservative treatment

**Negative Surgical Correlates:**
- smoking
- poor physiology
- diabetic / immunosuppression
- previous surgery
- obesity / de-conditioned
- chronicity – i.e., more than three months of symptoms since injury
- retraction or atrophy of thigh musculature
- multiple physician or caregiver involvement

**Rehabilitation Protocol (post-surgical):**
- 2 to 3 times per week for 4 to 6 weeks (extendable)
- re-evaluate every 4 to 6 weeks by clinical and treating physician
- physical therapy for three month maximum, accumulative in nature with the exception of special circumstances

### GOALS OF TREATMENT

**Recommend RTW:**
- Non-Surgical:
  - generally light duty within 3 to 4 weeks
  - full duty within 6 to 8 weeks for most cases
- Surgical:
  - light duty within 4 to 6 weeks for most surgical interventions
  - full duty within 6 to 8 weeks for most surgical interventions
  - potentially longer (3 to 4 months) for extensive ligament reconstruction or arthroplasty with some vocations
  - contingent on assessment of functional capacity predicated on the treater’s judgment with second opinion when appropriate

### IF GOALS NOT MET

- Consider alternative cause.
- Consider psychological and motivational factors
  - see Psychological Guideline
- Second opinion:
  - after 3 to 6 months of non-surgical or conservative treatment without benefit
  - after 6 to 12 months postsurgical with poor result
- At any time during treatment, the patient should be given the option for second opinion, if there is an apparent physician-patient problem.
